I need a pointer to some info on how to
do a VHF stripline design for parallel
ceramic tubes.
Have not found much info on this subject on
the net nor in my collection of hambooks.

>among other things. Any comments as to how acurrate, how difficult to use, how

I haven't used ARD, so I can't comment. I just thought this would be a good thread to throw in a plug for the programs that come with Wes Hayward's book, "Intro to Radio Frequency Design".

I've been fooling around with these for a few weeks, in support of a receiver project that I'm working on. No spiffy windows interfaces or anything here... they were written for DOS so that they'd work on a maximum number of PCs. There's programs for just about everything you need to do when designing a radio, and several of them let you very easily play with the various trade-offs and see how they affect your design.

There is no electrical simulation program in the package, so you need to more or less know how your circuits work. There are a couple of transistor amplifier bias/gain calculators to help you. "FBA" uses the hybrid-pi bipolar transistor model to give a reasonably good approximation of what you'll get out of your circuit.

Other goodies I've used: "GPLA", a ladder-circuit analysis tool, very handy for designing filters, diplexers, etc. "CASCADE" lets you build a simple gain/noise/IMD model of your radio, and then tweek it. It will do sweeps, for instance, sweep the gain of your preamp from 0 to 20 dB and report results. Very handy for optimizing gain distribution. "SPURTUNE" helps in finding spurious responses and birdies.

You need to do some interpretation of results yourself with these. They won't really help if you don't know what gain/noise/IMD are, but they do a lot of the grunt work for you if you do. Worth the price of the book, which is very good, too!

Other than filter availability - check the surplus stores for big bags of microprocessor clock crystals (not to mention colour burst crystals and the like), as well as available prepackaged filters - other issues for choosing an IF are related to feedthrough and spurious responses.

As an example, an IF of 7200 kHz would be one to avoid, due to 41 meter shortwave broadcasters getting into the IF. An IF that is harmonically related to other oscillators in the radio is one to approach cautiously. What's on the image frequency? Can you filter it? Check for spurious responses in the IF, like 3rd and 5th harmonics of the VFO mixing with things.

Tune around with a general coverage receiver. Check the frequency allocation tables. Above all, have fun and keep us posted!

>Yes, but your "classic" rig doesn't tune backward on 75m. Gary's does.
>And you might want to move your IF up a couple hundred kc ...

OK, we're getting there slowly. What Gary said was:

>(note tuning is backwards on 75m and sidebands invert, this is the
>historical reason why 75m uses LSB and 20m uses USB).

- but as KO6KA pointed out, the sidebands from a 9MHz SSB generator actually don't invert between 75m and 20m, they have to be deliberately switched. So we can agree on: "tuning is backwards on 75m, and IF the sidebands are also inverted, the rig tunes the same way on both bands".

Well and good... but that can't be the whole answer, because the USB/LSB split actually pre-dates the 9MHz SSB exciters.

As Wes, N7WS pointed out, the original 9MHz phasing exciters came *after* the earlier filter rigs which generated SSB at 455kHz or lower. 9MHz phasing became popular as a result of influential articles in 1950 and 1956, and 9MHz filters didn't appear until about 1960.

Note also that these were transmitters only. Receivers were separate at that time, and they tuned the same way on all bands. Therefore they had to be tuned in *opposite* directions to resolve LSB on 75m and USB on 20m.

A 1950 QST article by W1DX on 'How To Tune In a Single-Sideband Signal' gives an LSB example at 75m. This and other QST reprints in the 1962 edition of ARRL's 'Single Sideband for the Radio Amateur' clearly show that the USB/LSB split was in place well before 1960 (which is also where my personal memories of SSB begin).

The real answer probably lies in pre-1950 QSTs - possibly the original articles reporting the "opening" of first 75m and then 20m by Villard, W6QYT at the Stanford club station W6YX in 1947.

That's as far as I can take it. My late father-in-law's 1950 ARRL handbook gives a list of the earlier QST references, so does anybody

want to look them up?

>factors should be considered when selecting the IF?

Well, if you're gonna go with commercial IF filters, I think you're pretty much
stuck with 10.7 or 9 MHz, and/or 455 KHz. A little pricey (say $50-$100), but
they'll do exactly what you want with very little fuss.

If you aren't shaken by the thought of building your own crystal filters, you
can use the pretty good selection of microprocessor crystals that are
available, or get some custom ground on any freq you want. It's not *too*
difficult to build one, but it takes some work and some test equipment.

Either way, you have to play with the numbers for image rejection, IF
feedthrough, and spurious responses with your selected IF freq. The farther
away from 14 MHz your 1st IF is, the better the image rejection and IF
feedthrough will be, depending on how tight your front-end filtering is.
That's why many modern multi-band HF receivers have 1st IFs up in the VHF
range. Spurious responses are harder to give a quickie rule of thumb for...
you just have to play with the numbers and see what happens. The 2nd IF is
considerably less critical, 'cuz a lot of tight filtering has already occured
and stripped off most of the possible problems. Do the spurious response check
for it.

7. Antenna Tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-01 00:00:00 UTC
From: lweide@rastro.Colorado.EDU
Message-ID: <lweide.838926970@rastro.Colorado.EDU>
Source record: 103590

Hi folks,

Would someone out here have some information/plans on a simple antenna tuner for an end fed 60'-70' line for the AM broadcast band?

I'll be using it primarly for testing and playing antique radio "stuff" in my shop. Sometimes I'll use it for crystal sets and comm receivers.

Thanks, Larry

>it be to convert to 10M am.?

Should be easy. You'll have to order custom-cut crystals from JAN or
some other crystal maker, then re-align the units. That should be all.
Larger CB shops might even have a Sams Photofacts manual on the HTs.
Check into that before you start. If there isn't one, or you can't
get ahold of it, go to Radio Shack and purchase the service manual.
It will be handy to have, especially the alignment procedures.

10. AEA RL-1: Anyone re-written software for this remote control?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-01 00:00:00 UTC
From: frohro@wwc.edu
Message-ID: <frohro-0108961707500001@hrf.wwc.edu>
Source record: 103593
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.digital.misc

Back in 1993 I purchased an AEA RL-1 controller. It was frought with many bugs, so many in fact that after expending around $500 and many many hours, I gave up on it with the idea that someday I would either dis-assemble their code and try and stomp the bugs or re-write the whole program. I still haven't gotten around to it. Back then I had some correspondence with several others who had similar experiences and ideas. I am wondering if anyone has proceeded any further than I have.

I did chat with AEA today, and as far as we could tell they haven't addressed any of the problems I had in their updates.

Please send me a note if you are interested or if you know anyone who might be or anyone who has worked on this.

Thanks,

Rob KL7NA/W7

16. Help needed with small broadcast type plastic variable caps

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-01 00:00:00 UTC
From: rboggs@pcc-uky.campus.mci.net
Message-ID: <3201418d.77537761@news.campus.mci.net>
Source record: 103599

Hi all,

Could someone tell me how to sort out the little plastic variable caps? It is the usual type that has 3 commons, 4 trimmers, and a total of 6 leads from the edges. I want to build a tiny T-match tuner similar to the 'QRP Delight' from 73 magazine and don't know what goes to what with these caps. I can measure capacitance with an Autek RF analyst, but I just can't figure out the sections. The leads are not marked O C A for oscillator, capacitor, and antenna,

Thanks in advance and 73,

Roy KE4KDT

I have about a dozen of these left after offer to
boatanchors group.

They were designed for inverters for mobile tube type gear and
are in excellent condition woth application notes.

DC input 12.6 volts
DC output 600volts at 200ma
Average switching frequency 2500Hz

Ap note uses a pair of PNP transistors some caps and some resistors.

Transformer has CT primary for 12.6volt
Dual primary that can be wired CT or bucked with primary for
switching bases.
Dual secondary that can be wired CT or parallel depending on needs.

$10//each plus shipping.

US Priority mail $3 for one $6 for two $8 for 3 $10 for 4.

> Robin
> email : workshop@pcm.co.za

Robin,

The 310 ohm resistor is used as a coil form for the 1 uH coil
(see the circuit and description for L5 on page 152 as an
example of this). Keep in mind that carbon resistors are not
resistors at 100 Mhz. The idea is to use the parasitic capacitance
of the "resistor" and the parallel, 1 uH, inductance as a resonanant
tank at 100 Mhz. The "resistor" doubles as a coil form. When
resonated this way, the high impedance of the tank is transparent
to the matching network and effectively decouples the power supply
from the amplifier output. In addition, at lower frequencies where
the transistor has higher gain, the now non-resonant tank has a
low impedance. This helps to prevent parasitic oscillations at
undesired frequencies, that can otherwise occur, by loading the output.

This is not mentioned in the example anywhere, so I see why
you may be perplexed.

Combining a HT and a 100 Watt brick for mobile operation is about the worst
setup concievable. Neither the quality of the RX nor of the TX will
be adequate for the range available at 100W out.

You may find a simple mobile rig *designed* to put out 50W
much better.

Anyway, if you want to try, you can look up the Motorola home page,
they have designs in their data books.

On July 5th, we moved to our own domain name at www.hamradio-online.com.
Unfortunately, the company we rented server space from announced on July 13th
they are leaving the web hosting business. Thanks to California Wireless, Inc.,
we have moved Ham Radio Online to their server which you can access for now
using this IP address:

http://206.13.40.11/

We are working to get the www.hamradio-online.com domain name redirected to the
new web site. In the interim, please use the IP address shown above. The new
web server is located in California's Silicon Valley so west coast readers
should see relatively good performance.

We also have begun adding August articles.

25. w1fb univ RX + TX?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-02 00:00:00 UTC
From: timhynde@ix.netcom.com
Message-ID: <4trt3h$9n7@dfw-ixnews8.ix.netcom.com>
Source record: 103605

Hi gang,

Question:

My universal RX from the w1fb qrp notebook is working swell on 20m, I have also built a 2 watt TX using a crystal, any reason why I cant take the VFO signal from the RX buffer it, and drive the TX with it? I know the VFO on the RX is not super stable but it's not bad, just seems to me like everything is there so why build another VFO just for the TX.

With a DC RX is the VFO running at the exact RX freq or shifted by some amount?

Thanks,

Tim ka8ddz/QRP

This is a bunch of cr*p. The "NO CODE" Tech has allowed the HAM numbers
to grow. With growth comes more representation and business. What
would happen if HAM numbers start to decline as they were in the
past? There is safety in numbers regardless of how one obtains a
HAM license. If you do not believe this just look at the recent
FCC Bands on the selling block.

I'm always amazed at this self-serving attitude. Regardless of anyones
opinion the truth of the matter is that a "NO CODE" Tech exists
today and was backed by a majority. How about coming down off the
pedestal and joining the rest of us "Sub Standard People"!

Buffer it well, and take particular care that VFO is well shielded
from TX signal.

You need to shift the VFO a bit (700 Hz, or whatever pitch you prefer
to listen to CW at) for tx. Up or down both work OK, just depends
on wether you want to always have to tune above or below other guy.

One nice way is by switching in a variactor for recieve...the
variactor voltage can then be varied as an RIT control.

Best not to have a variactor in circuit for TX if you can avoide it,
as they tend to be temp. unstable.

Case for seperate VFOs:

Nice to be able to work DX split.

You can exactly zero beat the other ham's freq. I have a 250Hz CW
filter on my TS-520, and it is very common for stations answering my
CQ's to be too far off to hear. ('520 transmits through this filter,
so don't tell me I have an offset problem)

You can use TX vfo as a "memory", tune the band with the RX, and come
back to TX freq. later.

With DC reciever, it is nice to have option of tuning either side of
RX signal, as one way will normally have worse QRM than the other.

Harder to verify TX is working, if sharing one VFO.

You can use the two VFOs to check each others calibration.

Hi Larry,

Get your hands on an ARRL antenna handbook (or *the* Handbook) and take a look at L network for matching to an end fed wire antenna. You will ned arrangements for changing the configuration of the L network to cover all that you want, but that could be a simple as changing some alligator clips for casual receive use. The length of wire you want to use is shorter than a half wave on some bands (BC particularly) and longer on others... thus the requirement to change the network. I hope that is easy enough.

Hi,

If you mean you are looking to replace an antenna and receiver to listen to the ham bands there are probably legal restrictions blocking the way. While it may not always be illegal, it usually would be illegal and most of us won't be connecting our radios directly to the net.

Children. children!!

This is approaching the combustion point!! The original post was nitpicking about "reciever" being mis-spelled. I wonder if anybody would really be confused by "reciever" and wonder if instead of a detection device it referred to a special dipole antenna or a bar of soap!!

There is already a "code endorsement" on some ham licenses. The general code endorsement is 13 wpm as is the advanced. The extra is endosed at 20 wpm and some of the other license classes have specific endorsements of 5 wpm.

Lighten up a bit. If you're going to use CW prosigns on *TTY* try to use them correctly before you complain about spelling.

I like CW... so do many others that weren't to lazy to learn it,
too many people want something for nothing. MAY IT LAST FOREVER!
The NO CODE ticket proved that if you give it away for the most part you
will receive sub standard people. There are many GOOD no code hams but
there are many more who should not be hams and have no respect for the
hobby and nothing to give. Those that learned the code for the most part
are good amateur radio operators, there are a few that are not. Again
they were forced to learn if they wanted something (a ham ticket).When
you give it away that's what you do GIVE IT AWAY!

>Bernie, WR3E.

You have noticed a common usenet problem... some 20.000 newsgroups
were created for discussion about many different topics, yet some
people cannot be bothered to check if their posting matches the topic
of the newsgroup before posting.
The result is often called "noise", and the "signal/noise ratio" of a
newsgroup can be varying, much like the s/n ratio when receiving a DX
station.

Then there are those loud mouth postings, like Dave's. Those guys want
to let the world know they have something *very important* to tell, and
post it in as many newsgroups they can think of. Those postings are
allmost certainly off-topic.

I'm afraid it is difficult to overcome. You will just have to live
with it, and select news software that allows you to quickly skim
articles to see if they are in the "signal" or in the "noise" category.
Some news software will also allow you to automatically skip articles
that are posted to many newsgroups. That will help you to avoid some
of the utter garbage (like "visit my page!" or "make money fast!").

73,
Rob

The formula for building antenna? Sorry I missed that one!!

To build an antenna you go outside and string lots of wire in the trees. You hank on a feedline to the radio from some where on the wires (pick any handy spot). Then you cut off all the parts that don't work (called pruning).

This approach has worked well for me but sometimes, after cutting off all the parts that don't work, all I have left is the feedline and half of a tree!! Whenever that occurs... start over.

Has anyone out there built the Roanoke Doppler DF unit described in "Transmitter Hunting ..etc." by J Moell and T Curlee ? If so, can they confirm that there are no errors in the schematic diagram (Fig 9-5) , please.

I am having trouble with what should be the easy bit, the audio amp/ low pass filter. With the component values shown I am not getting the signal levels quoted in the text. DC voltages are close to spec. The digital bit works fine, so far.

Whilst I check my wiring (again!) I would appreciate some reassurance from any successful constructors.

Thanks.

Tom

>
> Gary-
well Gary as I said there are some good no code hams. By the way I
supported the no code ticket, only now to wish I had not ! I also do
testing for Amateur radio (VE) so there !! What I do, is give the
lessons for the ones wishing to take the test and instruct them about
proper radio manners, most people however do not get this extra
attention and I have seen a large number of the new NO CODE Hams
SCREWING UP AND ACTING LIKE THIS IS A CB and 90% never upgrade! This has
become so bad that many older hams have petition the FCC to change the
NO CODE TECH. ticket to be a 2 year ticket requiring an upgrade to keep
the ticket active. Numbers are not everything, if the ham band is to
become a SUPER CHARGED
C.B. band then sell it all! Oh by the way before you start making
assumptions I was once on the CB band and left because of no respect for
fellow operators or the rules and regulation and yes there were rules
just no one followed them much like what I'm seeing now. Did you know
that the 11 meter band (CB) was once a ham band ! So I suppose you are
either a no code ham or someone who just wishes to be heard but really
has no idea as to what he is talking about. Have you listen to the local
2 meter repeaters in your area, jamming, cursing, call for hey good

buddy, I didn't hear all this before the No Code Ticket came along. Now to change all this we as Amateurs need to in-force the rules and stop the foolishness going on before we all lose, CW operators and NO CODE alike. All I want to see is order on the bands I don't care if you or anyone else ever upgrades as long as you conduct yourself as a ham operator not some jerk off of channel 19, 10-4 good buddy ? If you do not fall into this category then you have nothing to be upset about code or no code. If it weren't for people like myself who try to keep this hobby alive there would be no NO CODE Ticket but I do feel that a NO CODE ham should learn more and not stop just because he has received a ham ticket! they should have restricted the NO CODE to say 6 meters and an upgrade test to other parts of the VHF spectrum this would have kept them learning instead of giving them the entire VHF spectrum.

If you like to build stuff, you might want to seriously consider making yourself a CNC rig. (Computer Numerical Control, usually of machine tools).

With a CNC, you can easily automate PCB drilling, making slick cabinets and panels (cuts odd shapes like D-sub holes easily).

The company I work for offers low cost CNC control software, and you can use surplus stepper motors, make your own L/R drivers, and buy or make some kind of XYZ mechanism. A dremel tool or laminate trimmer completes the rig.

For serious metal working, a drill press and one of those $100 X-Y tables can get you started, although a $995 mill/drill is vastly more useful, accurate, and powerful.

Please call Ah-ha! direct if you want their free catalog. I don't do the paperwork stuff. CNC is an incredibly powerful addition to a small shop.

Good Luck!

>> a signal my be sent quickly and with clear reception?
>
>The *main* factor is the receiver.

Beyond line of sight, the main factor is *propagation*. Antennas can be important, and the receiver certainly is (but Marconi used a glass tube full of iron filings to span the Atlantic). The modulation used makes a difference, and transmitter power is the catchall factor. The frequency chosen is also an important factor since it influences all the other factors. The whole thing has to work as a system.

Signalling speed (baud) for terrestrial beyond line of sight paths is determined primarily by multipath. Operating near the MUF (for ionospheric paths) will reduce multipath, and coherent M-ary modulation with proper coding can resist it. At VHF+, antenna directionality and siting are the largest factors in controlling multipath. Good modulation choices (such as SS) can resist its degradations.

For free space paths, SNR (and available bandwidth) dominate as the factors controlling signalling speed. Coherent modulations again help in resisting degradation by low SNR (incoherent OOK is a poor choice, incoherent analog modulations a worse one). A stronger transmitted signal directly affects channel SNR. A good receiver can avoid excessively degrading channel SNR (both through using low noise devices to avoid contributing to channel noise and by using matched filtering to avoid passing out of channel noise), but it can't improve channel SNR. A directional antenna can effectively improve channel SNR over isotropic by restricting the noise coming from other directions on channel from reaching the receiver.

Assuming adequate techniques are used for each link in the chain, for a given frequency, the order of importance probably goes like this;

1) Propagation
2) Antennas
3) Modulation
4) Receiver
5) Transmitter

Propagation dominates, and is the largest loss factor and the
largest factor contributing to multipath. Antennas couple to the
propagation path and thus are key elements. The modulation chosen
determines how well the signal can resist the various impairments
caused by propagation. The receiver must avoid degrading channel
SNR as much as possible. And finally, enough transmitter power
must be used to overcome all the loss mechanisms. The amount of
transmitter power *necessary* is often surprisingly small, however.
With the correct choices of other factors, a few milliwatts can
easily span the globe.

Gary

Does anyone out there have an assembly manual for an HW-8 that you
would be willing to photocopy and send for a modest price? I can get
an unassembled one without the manual and was told that a replacement
would cost $35 from Heathkit. Any ideas?

You cannot go wrong with a simple L-network..

A coil with taps or alligator clips to make various taps and a
condenser (oops gave away my age) A capacitor also with
clips on both sides and a knob to turn the cacitor plates and your in
business....

the coil and cap can go in series, or paralell and there are lots of
combinations what will work really well....

i used on on a random wire and used a SWR meter between my transmitter
and the breadboard coil and cap and it worked very well...

I haven't followed this thread all the way from the beginning, but I'm amazed at how it changed from spelling to a discussion of the pros and cons of the no-code license class. Since I'm a no-code tech, I'm obviously for it. Where I see the problem of brain dead ham operators comming from is the publishing of the question pool. If the FCC published a study guide instead of the question pool, people would be forced to actually study and UNDERSTAND the information that they are being tested on. I know people who have passed the test by memorizing that the answer to a particular question was 'B'.

Wow! This had never occurred to me! I have an old AOR 2500 widerange monitor sitting here with a cute little DB-9 connector on the back and a manual full of commands that can be sent to tune and configure it. It seems it would be pretty straightforward to build some CGI to send tuning commands and hook the audio out to a RealAudio server.

Using this config, anyone with a web browser could grab my scanner and listen to what's in the air in Phoenix. Now the question is "Who cares?" Plus, I'd have to set up a web server on my Mac, leave it running and on the net all day. Sounds like a project for someone with an existing server.

Interesting idea though.

Hi Steve:

I used a 35W amp with my HT in the car for a while with a 5/8 wave mag
mount from Radio Shack. It work quite well. The amp came from Tucker.
I am looking at their new catalog and they have gone to a new amp with
their name on it but it still delivers 35W with a 15 db preamp for $99.

It might be illegal to connect the licensed station to the net. It might not, too. I did not say "listening to a radio" is illegal! How does the FCC regard this media? Are we retransmitting amateur signals (for moentary gain)? Is anybody (including the service provider) receiving any money for the relay or rebroadcast of these signals?

PLEASE don't ask the FCC!! It sounds like a lot of people are getting a lot of harmless enjoyment from this. If you are involved in the actual connection for the relay or rebroadcast... keep an eye over your shoulder.

Start by looking at the smaller power FETs. You may have some stability problems at the power levels you want. Might be better off with a lower power oscillator and follow it with your 28 volt power stage.

The FCC has issued new rules regarding the evaluation of RF Emissions and
health effects from all transmitters. As always, the devil is in the details
and the details say that if you transmit over 50 watts, you may have
to perform an RF emissions environmental assessment of your Amateur station.
Under the new rules, the FCC will add five more questions on RF safety to three
of the written exams. Amateur radio operators will be required to certify as
part of their license application, under an as yet unspecified mechanism, that
they understand the FCC rules on this issue. In some situations, certain
Amateurs may have to file a complex "Environmental Assessment" better known as
an Environmental Impact Report regarding their Amateur station operation.

You can read the complete text of the relevent FCC ruling in FCC 96-396 at

Recently a rival club installed a 144.93 node just 100 ft away from
our clubs 145.01 MHz packet node. The ARRL VHF manual suggests that
a horizontal antenna separation of 1 mile or more is required to
avoid desense at a 600 KHz repeater pair. In this case, we are only
dealing with a 80 KHz frequency separation. Our node is using a
Micor radio. The 144.93 radio is running 5 watts.

The other club insists there will be no desense to our node. Does anyone
on this group have practical experience on what minimum frequency
spacings should be when radios are operated in the immediate physical
location?

69. Please Help with 10GHz Microwave Gunn Diode Assembly

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-04 00:00:00 UTC
From: sidener@crunch.nuc.umr.edu
Message-ID: <4u37un$rp@hptemp1.cc.umr.edu>
Source record: 103549

Hi, I need some help fixing a Microwave Associates 10GHz Gunn diode assembly.

the model is : MA 86656 CM

I have two of them and I am trying to make a amateur data link but one of them has no output when I apply the voltage to the diode. I noticed something rattling around inside the assembly so I took out the plunger which holds the Gunn diode and found that it had slipped out of it's holder (probably from being dropped). I replaced the diode in the holder and tried to fire up the assembly again. Still no output. I do not know which way the diode goes in so I tried both directions (there are no markings on the diode) Still no output.

I can only assume that the diode is bad, but I have no idea how to find another. It has no numbers.

If anyone has any specs or advice on obtaining another Gunn diode or the correct orientation, I would appreciate any help I could get.

I was told that one of these assemblies cost around $500 new, and I don't have that kind of "hobbie" money avaliable. So I would like to fix the one I have.

Thanks,

Scott Sidener N0WFL

It sounds like you do have a bad diode. You can check the direction
it goes in by looking at your other assembly.

I have some 10 to 20mW Gunn diodes that were used in motion detectors
that might work. Contact me by direct email and we can describe our
respective package types to see if mine are mechanically identical.

_____________________________________________

1.0 What is BASIC Stamp ?
-------------------------

This is being written for people who have no idea of what a BASIC
Stamp is...

BASIC Stamps are small reprogrammable single board computers (SBC)
that run BASIC programs and are made by Parallax, Inc. in US. At
first glance, they may seem fairly minimal - and in fact, they are.
But with software that fully utilizes all available hardware, the
Stamps give you powerful features - without the cost of hardware.

Their low cost and simplicity make the Stamps perfect for many
prototyping and control applications. It's suitable for electronics
hobbyists as well as electronics professionals in many different
areas.

Typical application areas for BASIC Stamp's are...

- General electronics
- Home automation
- Robotics
- Mini PLC
- Education
- Prototyping
- HAM related applications
- Special effects in films
- Industri control
```

- Geological instruments
- Computer peripherals
- Scale model hobbyists
- Model train hobbyists

As an talent engineer and technical writer expressed it...

- BASIC Stamp is the 555 of the 90's !

1.1 What is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great ideas and many problems that are solved with the BASIC Stamp and the main purpose of this list is to get an idea of what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

Remember it's up to all of us if this list are going to be any good and I'm looking forward to receive a description of your application.

1.2 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that you are willing to tell others please use the form given below and write a short description, nothing fancy is needed just a simple explanation. If you have source code to share that's even better but it's not necessary.

Then e-mail the form to:

cj@hth.com

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in the L.O.S.A form on the Web-page...

http://www.hth.com/losa.htm

[--- cut ---]

1.3 Where could I find L.O.S.A ?

The latest version of L.O.S.A is going to be posted to the following
mailing lists and news groups, I will update it approx. once a month.

Mailing lists:

BASIC Stamp Mailing List

News groups:

comp.robotics.misc
comp.home.automation
sci.electronics.misc
rec.radio.amateur.homebrew

FTP-site:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

You can also find the latest version on the following URL...

http://www.hth.com/losa.htm

If you don't have access to Internet you could send an SASE to the
address given below and I will return you a 3.5" DOS-disk with the
latest version in ASCII-format.

=========================================================================
Title : Robo-Cat [# 001]
=========================================================================
Date : 950807
Author: Gustavson Guy W.
E-mail: GWGUSTAVSO@mpg.norstan.com
-------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: N/A
Filename : N/A
URL : http://www.winternet.com/~bigfoot/cat.html
-------------------------------------------------------------------------
Description :
```

My cat, Kesha, was recently diagnosed with Heptic Lipodosis. Or "Fatty Liver", basicly what this means is that for some reason he stoped eating and his liver started converting body to useable sugars. The fat deposists biuld up in the liver and cause severe liver damage. Because the liver isn't working well the cat feels crappy and wants to eat even less. The treatment for this disease is to run a tube down down the cats nose into his stomach, or a PEG tube through the abomine wall into the stomach and feed the cat a liquid diet this way.

I love my cat, but I can't be there every three hours to feed him through the tube for a month. Something about work and deadlines and such. So I went to a local supplus house and got a tiny motor driven pump, a case, some switches, a micro switch, ect...

The micro switch is mounted such that the switch trips for every rotation of the pump shaft. The stamp turns on the pump for on a single rotation at intervels programable from the controll switches on top. An alarm buzzer and LED flash if the pump fails to run for any reason. The unit is programable for 9 differents deleviery rates.

Now he gets a slow continuious feeding and he seems to tolerate this better than the 100ml feeding every three hours.

==========
Title : Logic Rudder [# 002]
==========
Date : 950812
Author: Christer Johansson
E-mail: cj@hth.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : LRUDDER.ZIP
URL : http://www.hth.com/filelibrary/BS1-IC/

Description :

Many of the new and very realistic flight sims available today needs rudder to let you get full control. This one uses a digital pot from Xicor (X9104) and 10 other components. Connects to a standard IBM-PC game port and power is taken from the port.

It uses two micro switches for controlling the rudders left or right and to indicate when rudders move there is a red LED that lights up when you press the micro switches and to indicate center there is a green LED. If you press the both micro swithes the rudder will automaticly return to center position.

There is a trim pot to set the desired step rate from slow to very fast and the Xicor pot has 99 steps wich gives a fair resolution.

==========
Title : Interfacing MAX186 8 channel 12bit A/D [# 003]

```
==========================================================================
Date : 950925
Author: Helmut Fligge
E-mail: h.fligge@asco.nev.sub.de
--------------------------------------------------------------------------
Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : N/A
--------------------------------------------------------------------------
Description :

This Program interfaces the Stamp1 to the MAX186 A/D converter. Via
RS232 2400bps the stamp is asked to measure channel numbern. After
conversion the result will be returned to the host computer as an
ascii string (0 .. 4096). Conversion rate is about 4 measures per
second.

==========================================================================
Title : Scrolling LED Sign [# 004]
==========================================================================
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org
--------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: Maybe sometime
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html
--------------------------------------------------------------------------
Description :

Scrolling LED sign, 35 super-bright LEDs in a 5-by-7 matrix in the
prototyping area of a Basic Stamp rev D. A scrolling alphanumeric
message moves one pixel at a time, just like real scrolling LED
signs, except this one only displays one full letter or portion of
two letters at a time as the message moves by.

==========================================================================
Title : Tone Decoder [# 005]
==========================================================================
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org
--------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: Soon
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html
--------------------------------------------------------------------------
Description :
```

Listens for telephone touchtones, displays phone numbers on LCD screen and echos them out RS-232 port. Circuitry fits in prototyping area of rev D Basic Stamp:

Microphone preamplifier, touchtone decoder IC.

```
=========================================================================
Title : Pager [# 006]
=========================================================================
Date : 950928
Author: Don McKenzie
E-mail: donmck@labyrinth.net.au
-------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PAGER.BAS
URL : http://www.labyrinth.net.au/~donmck
-------------------------------------------------------------------------
Description :
```

This program for the Basic Stamp is used to monitor 4 hardware signals. If a change takes place, (after testing for a false trigg- er) then a cheap 2400 baud MODEM is used to dial into a Telecom Alpha-Numeric pager. It leaves a message which consists of a 2 digit I.D. (01 to 99) followed by the 4 signal levels of pins 3 to 0.

Status of the signal levels message: 0=Low, 1=High. EG: "011110" means Unit "01" has pins 3, 2, and 1 high, and pin 0 is low.

A "Ring-In" feature is also included. By ringing the MODEM for a short period, then hanging up, the Stamp will dial your Pager and report the current hardware status of these four signals.

This program uses about half of the available memory, so if the user wishes to add enchancements such as "Multiple Ring-In's" say within a minute, for a command selection, there is plenty of program space left.

```
=========================================================================
Title : HexWalker Mobile Robot [# 007]
=========================================================================
Date : 960511
Author: Tom Thornton
E-mail: mandtsys@ix.netcom.com
-------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D or BS1-IC
Code available: YES
Filename : WALK.BAS
URL : N/A
-------------------------------------------------------------------------
Description :
```

HexWalker is a hexapod robot that exhibits obstacle avoidance behavior. It is controlled by BASIC Stamp, BS1-IC, or Stamp chipset

(PIC16C65 + EEPROM). Driven by three servos it is the simplest machine architecture that can walk forward and backward, and turn left or right. A kit is commercially available contact author for details.

==========
Title : Robo Bug [# 008]
==========
Date : 951003
Author: David Novick
E-mail: dkn@cimar.me.ufl.edu

Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : http://www.me.ufl.edu/~dkn

Description :

Using two stamps, a robot with six legs (2 degrees of freedom each) was able to walk and turn (at this stage, not very gracefully).

==========
Title : EXPBOT Robot controlled by Stamp [# 009]
==========
Date : 951009
Author: Marvin Green
E-mail: marvin@agora.rdrop.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : EXPBOT.BAS
URL : E-mail author and he will send it

Description :

This program allows a cool robot to move abound a room in search of light. Like a moth. Simple program changes can dramatically change the robots behavior.

==========
Title : Andrews Ever Evolving Lego Robot [# 010]
==========
Date : 951119
Author: Andrew H. Hochheimer
E-mail: softarts@ciaccess.com

Stamp model : BS2-IC
Code available: YES
Filename : N/A
URL : http://www.wincom.net/~softarts

Description :

Currently the robot can only navigate to the brightest light source in a room. It's current operation mode has four major steps: - Scan a 180 Degree Field of "Vision" taking light level readings, and determining the brightest direction of light. - Decide if it needs to turn left, right, or continue moving forward. - Check for collision with an object while moving, if a collision occurs, display the total travel distance on the display - Move forward for 1.5 Seconds and then repeat the process.

Currently I am using Two Futaba FP-S128 Servos (any RC Car Servos would work) one to sweep it's "sensors" form left to right, and one to "stear" the robot.

You can see pictures and more information on my homepage, just follow the lego robot link.

==========
Title : Factory Monitoring System [# 011]
==========
Date : 951120
Author: Paul Willemse
E-mail: pjwill@merlion.singnet.com.sg

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : N/A
URL : E-mail author

Description :

The system presently consists of 4 Basic Stamp units. Each monitors up to 5 inputs. The inputs are 'digital' (switches) and/or analog (temp, airflow, current, etc using commercial sensors). All stamps communicate the results via serial mode to a Macintosh (Yes a Mac!) where the results are graphically displayed and monitored. Alarms are set for certain conditions.

The transmission is simple, one way only. Each stamp sends the info at a 'random' interval not exceeding 2 seconds. The message format is fixed, the Mac will throw away any conflicts in case two or more stamps transmit at the same time. BTW this happens very seldom. The max time any stamp can be 'absent' from the chain before an alarm is raised is six seconds (failure, transmission collisons, etc). This is controlled by the Mac.

The 'system' is presently in beta test, the client wishes to expand up to 20 stamps. At that point we will likely use the BS1-IC or BS2-IC on custom boards located around the facility.

Code is available upon request (e-mail) partial, some is proprietory to my client.

```
=============================================================================
Title : Wave to the Cats/Desk Temperature [# 012]
=============================================================================
Date : 951121
Author: Paul Haas
E-mail: paulh@hamjudo.com
-----------------------------------------------------------------------------
Stamp model : BS1-IC
Code available: Yes
Filename : See web server
URL : http://hogwild.hamjudo.com/cgi-bin/stamp
-----------------------------------------------------------------------------
Description :

The Stamp has a serial connection to web server, a cardboard hand, a
servo motor to move the hand, and a DS1620 thermostat chip to meas-
ure the temperature. The web server can request the current temper-
ature or start the hand waving. See the web page for the source code
for the temp and the web server.

It's mostly useless. The cats ignore the hand. A few people find it
entertaining.

=============================================================================
Title : Gamer's Die Roller [# 013]
=============================================================================
Date : 951122
Author: Larry Tremblay
E-mail: ltremblay@domus.com
-----------------------------------------------------------------------------
Stamp model : BS2-IC
Code available: N/A
Filename : N/A
URL : N/A
-----------------------------------------------------------------------------
Description :

The Gamer's Die roller is a little thing I am putting together as my
first Stamp Project. The Roller allows cumulative rolls of n dice up
to 256 sides, so long as the sum does not exceed 99,999,999(!)

It uses two 74HC161 4 bit counters cycling at 1MHz to draw random
numbers off of. Input is achieved via a Grayhill model 38 keypad
and a 74C922 keypad decoder. Display is on a Siemens PDSP-2111 8
character smart display (5x7 LED characters) fed by two 74HC164
serial to parallel shift registers cascaded so I can use Shiftout to
feed 16 bits of control + data off of 2 pins.

The code is very simple, the most exotic part being the random numb-
er generation. In a nutshell, it is:

Begin Loop
S = 8 bit number drawn from the counter (random)
```

```
if S < (255/N) x N (integer divide, N is number of sides on die)
exit Loop
End Loop
```

This gets (pseudo) random numbers whose average is not skewed downwards by the counter's max of 256 (i.e. a 100 sided die is not affected by the extra 56 in the count maximum)

Using gamer's dice notation, (5d6 = sum of 5 six sided dice, 3d10 = sum of 3 ten sided dice), the user can input whatever combination they wish, including just 'd6' for one six sider. The keypad I have has removeable keycaps with legends, so I have 0-9 plus 'd' and '=' on them.

As noted earlier, since I am using an 8 bit counter, the maximum die size is 256, although that could be fixed easily by sampling two, three or more times for each die.

Anyhow, that's it. When the code is done and debugged, I'll be happy to e-mail it to any who want it.

```
==========================================================================
Title : Stamp II Serial I/O [# 014]
==========================================================================
Date : 951128
Author: John Hansknecht
E-mail: Hansknec@cebaf.gov
--------------------------------------------------------------------------
Stamp model : BS2-IC
Code available: Yes
Filename : HAL01.bs2 and HAL01.bas
URL : ftp.parallaxinc.com
--------------------------------------------------------------------------
Description :
```

A bare-bones demonstation of 2 way serial communications between a PC running Qbasic and 1 or more Stamp II's.

```
==========================================================================
Title : Voice and CW Fox Hunt Transmitter IDer [# 015]
==========================================================================
Date : 951221
Author: Sam Guccione
E-mail: sguccion@outland.dtcc.edu
--------------------------------------------------------------------------
Stamp model : Counterfeit Stamp
Code available: Yes
Filename : Revision of S. Edwards MORSE program
URL : N/A
--------------------------------------------------------------------------
Description :
```

An IDer based upon the MORSE program. Has 4 time delays as well as
a random time delay. Circuitry includes selection of a voice id
using the Radio Shack 10 voice board or the Walden bookstore 10 sec
talking gift card. This is a very simple circuit and program but was
developed by my students under my direction.

May be of interest to someone out there.

```
========================================================================
Title : Lift (elevator) Controller [# 016]
========================================================================
Date : 951225
Author: Dave Bell
E-mail: dbell@cup.portal.com
------------------------------------------------------------------------
Stamp model : Faux Stamp (BASIC Stamp clone)
Code available: Yes
Filename : Upon request
URL : N/A
------------------------------------------------------------------------
Description :
```

A simple control loop monitoring lift Call buttons (with debounce)
and Limit switches, forbidding manual control past limits, and en-
forcing a Stop before reversal of direction. This will be used in
an owner -designed and -built single story platform lift for a home.

```
========================================================================
Title : Paging with the Stamp [# 017]
========================================================================
Date : 960104
Author: Kurt Clement
E-mail: kclement@kraft.com
------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: Yes
Filename : monitor.bas
URL : N/A
------------------------------------------------------------------------
Description :
```

Use the Stamp to monitor several inputs, two temperature and two
contact closures in this application. When inputs go outside set
limits, dial pager and send coded message. Used to monitor power
failures and temperatures for computer and network equipment since
August 1994, running on 9 V power supply from one of the UPS units.

```
========================================================================
Title : Switching Sytem [# 018]
========================================================================
Date : 960109
Author: Alexander Avendano
E-mail: aavendan@aros.net
```

Stamp model : BS1-IC Module
Code available: N/A
Filename : N/A
URL : N/A

Description :

I'm almost finishing a Basic Stamp Based Switching System (Small Phone system) which I consider very usefull for small companies that cant'n afford other brands. This is designed with a host computer which will have a vox-mail and all the functions like big ones to choose. I'm using BS1-IC's for the extensions process right now.

As soon I have complete it I will give the code away for small Intelligent Switching phone system up to 2 Lines and 4 Extensions using the L.C.D serial circuitry for information display. I forgot to mention that the computer (Host for many processing functions) will be running under Windows 3.1 and Windows 95, making this way a usefull computer not only for the phone system but for ithers application at the office.

Please be free to send me E-mail, about any suggestion.

==========
Title : Door Entry Card Reader [# 019]
==========
Date : 960110
Author: Ed Buckley/J J Barbarello
E-mail: ed@milinst.demon.co.uk

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : N/A

Description :

Stamp 1 based version of the Card Reader article by J J Barbello as described in the August 1995 edition of Electronics Now. This version uses the Stamp 1 as a local controller determining the card number and deciding whether or not to allow door opening. Optional serial comms back to a master controller and optional local message readout using an LCD Backpack.

Lots of scope for further enhancement/experimentation. Circuit schematic and listing available.

==========
Title : Telephone Card Reader [# 020]
==========
Date : 960119

Author: Francesco Volpe
E-mail: f.volpe@ee.mu.oz.au

Stamp model : BS2-IC Module
Code available: YES
Filename : TELEMARK.LZH
URL : ftp://ftp.ix.de/pub/elrad/010/

Description :

The BS-II is used to read a German telephone card, which is a smart card. For more details see the German Electronic Magazine ELRAD (http://www.ix.de/el).

The data is transfered via RS232 to any terminal program.

==========
Title : DTMF Decoder [# 021]
==========
Date : 960125
Author: Joe Altieri
E-mail: radioman@banished.com

Stamp model : BS2-IC Module
Code available: YES
Filename : DECODE.BS2
URL : N/A

Description :

A new parallax BASIC Stamp II program for decoding a nine digit DTMF sequence of "Touch Tones" for remote activation/de-activation of any electrical appliance via Ham Radio, radio link, telephones, intercoms, etc.

==========
Title : Ion chamber radiation monitor [# 022]
==========
Date : 960125
Author: Jeffrey L. Rothman
E-mail: rothman@bnlls1.nsls.bnl.gov

Stamp model : BS1-IC Module
Code available: YES
Filename : RADMON12.BAS
URL : N/A

Description :

A Basic Stamp monitors the operation of an ion chamber radiation detector. The ion chamber and related circuitry produce a signal with a frequency proportional to the dose rate. The Stamp measures

the frequency and calculates the dose rate and total integrated dose.

The results are displayed on a log scale panel meter and an LCD respectively. The dose rate is also transmitted over RS-232 to a remote PC.

A Front panel button allows the user to reset the total integrated dose. Another button allows the audio alarm to be muted at low dose rates.

```
==========================================================================
Title : Barn Monitor [# 023]
==========================================================================
Date : 960203
Author: Lynn A. Roth
E-mail: lynnr@hesston.edu
--------------------------------------------------------------------------
Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : E-mail author
--------------------------------------------------------------------------
Description :
```

The Barn Monitor checks the temperature in 5 rooms of a farrowing house. The temperatures are taken by DS1620 chips.

If the temperature goes outside the limit set by the farmer, the Stamp dials a pager using a 2400 baud MODEM. The same occurs if the power goes out.

```
==========================================================================
Title : Dallas one-wire interface [# 024]
==========================================================================
Date : 960212
Author: Daniel G. Clemmensen
E-mail: dgc@shirenet.com
--------------------------------------------------------------------------
Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : http://www.shirenet.com/~dgc
--------------------------------------------------------------------------
Description :
```

As part of a furnace controller project, I've interfaced A Stamp II to a string of Dallas 1820 digital thermometers. The interface consists of three cheap IC's and some subroutines. A design note and a demo program are available on the web. I have successfully tested the interface with a string of twelve 1820's.

I have not yet tested it with other one-wire devices, although I
will update my web site when I do.

==========
Title : Sculpture control [# 025]
==========
Date : 960323
Author: Pierre Olivier
E-mail: olipie@aei.ca

Stamp model : BASIC Stamp Rev. D
Code available: N/A
Filename : N/A
URL : N/A

Description :

I have been working with sculptors for some time doing control cir-
cuits for their works using 555 (limited), industrial controllers
(expensive and hell to program) and lately Basic Stamp.

Our latest piece deals with image deconstruction: it consists of 20
vertical cylinders on which an image is wrapped. Each has a photo
detector to detect "position zero", and a custom basic stamp board
with a MC3479 step motor driver that drives a step motor which turns
one cylinder. Each cylinder can thus have its own routine which pos-
itions it precisely (400 steps/rev motors) where we want it for any
amount of time, at any speed (very interesting sonically at sub-
second stepping speeds!).

The stamp outputs direction, step and enable signals to the motor
driver and a ready signal to a common line. It receives signals from
the aforementionned ready line, and from the optical sensor.

It would have been quite a bit more complicated, bulkyer and
expensive to implement this project without the stamp.

==========
Title : Commercial clothes dryer controler [# 026]
==========
Date : 960401
Author: J Amy
E-mail: Kuznjack@aol.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : N/A
URL : N/A

Description :

Detects drop of coin and increments time remaining register.
Actuates main and heat relays. Checks temperature, and controles

heat relay Periodically decriments time remaining register. Provides cool down cycle in last four minits.

Replaces original controler which costs several hundred dollars, and is not reliable.

==========

Title : Morse Code Keyer [# 027]

==========

Date : 960415
Author: Richard Clemens
E-mail: clemens@academ.wvwc.edu

Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : http://www.ccue.org/stamps/morse2_bs2.html

Description :

This program provides a four message keyer for Amateur Radio. The user can input four different messages, their character counts, and use four buttons to display the output and/or key a transmitter.

NB: the messages are limited to the upper and lower case letters, digits 0-9, space, period, comma, ? and /

Program is based on the information in Stamp I - Note 8 and uses some code from that note.

==========

Title : Traffic Light Controller [# 028]

==========

Date : 960418
Author: M-Systems Inc.
E-mail: mstems@aol.com

Stamp model : BS1-IC Module
Code available: N/A
Filename : N/A
URL : N/A

Description :

We have used a BS1-IC to control a simple two way intersection coordinate the timing and switching of a traffic light at a two way traffic intersection.

==========

Title : Automotive Lamp Control [# 029]

==========

Date : 960427
Author: Ron Woodward

E-mail: RWoodward@gnn.com

Stamp model : BS2-IC Module
Code available: N/A (Will share concepts)
Filename : N/A
URL : N/A

Description :

This system involved connecting two BS2 units to a bank of 28 MOSFET drivers which controled the external lighting in a demonstration vehicle shown at the SAE expo in Detroit MI.

The lighting control had to perform PWM modulation simultaniously on 10 different circuits while controling Turn, Stop, Tail, Backup Hi Beam, Low Beam and fog lamp circuits with a set of preprogrammed timing sequences.

The timing was worked out so that the PWM of the lamps was flicker free throughtout the demonstration sequence.

The BS2 units worked together in a master - slave relationship to maintain proper sequencing of lights on both hands of the vehicle.

==========
Title : Single Switch Scanning Device for Disabled [# 030]
==========
Date : 960508
Author: Chuck Benson
E-mail: Chuck%6567006@mcimail.com

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : N/A
URL : E-mail author

Description :

This project modifies a Lanier VoiceWriter dictation device so that it can be operated by a person with a severe disability such as quadriplegia.

The interface to the device is via the VoiceWriter's hand contro-ller. The connections to the external switches are removed and replaced with switch closures via reed relays driven directly by the PIC's (BASIC Stamp's) I/O.

The user starts operation of the device by operating a SPST switch (typically with his or her cheek or jaw). The user then hears a series of five (5) tones which come from a piezo-electric speaker driven directly from an I/O pin.

The tones correspond to 'Play', 'Stop', 'Record', 'Rewind','Fast Forward'. When the desired tone is heard, the user activates the switch again and a relay corresponding to that function is closed. This in turn provides the desired function from the dictation device.

The code is a series of nested loops that provide the tone & the relay selection. Copies of code are available upon e-mail request.

==========
Title : Bell timer for school bell control [# 031]
==========
Date : 960511
Author: David Abineri
E-mail: dabineri@tso.cin.ix.net

Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : E-mail author

Description :

This is a sytem which allows flexible control of bell schedules for schools. One may program up to seven different schedules of 30 different times each. Data entry is with a small keypad. Indicators show the schedule currently being used and the day of the week.

Users may instantly select which schedule to follow and may even enter a special schedule in a matter of a minute or so. The system simply operates a relay that rings all the bells in the building. Editing schedules is allowed as well as manual operation.

==========
Title : RIMS controller for beer making [# 032]
==========
Date : 960802
Author: C.D. Pritchard
E-mail: cdp@chattanooga.net

Stamp model : BS2-IC Module
Code available: YES
Filename : N/A
URL : http://caladan.chattanooga.net/~cdp/index.html

Description :

Controls mash temperature on a recirculation infusion mash system (RIMS) and also controls the sparge water tank temperature. Uses thermistors to monitor temps- 2 on the RIMS and 1 in sparge water tank.

Controls AC power supply to two 1500W heaters via optoisolators/
zero-crossing driven triacs. Setpoints are entered via 4 keys.
Elapsed times, temperatures, setpoints and heater statuses are
displayed on a 2x16 LCD. Sends data via RS232 to a PC for logging
and analysis.

==========
Title : Stamp 1 and ISD 25XX Sound Chip Application [# 033]
==========
Date : 960605
Author: Ed Buckley
E-mail: ed@Milinst.demon.co.uk

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : E-mail author

Description :

Interfacing the Stamp 1 and the ISD 25xx series sound chips to give
an intercative demonstration of the Stamp's ability. The ISD 25xx
chips allow recording and playback of a number of discrete messages
up to a total of 90 seconds long.

The Stamp is used in this application to control the chips activities
in Operational Mode- message cueing. The Stamp looks for one of four
buttons to be pressed and then controls the ISD chip to play the
approprate message.

Great for simple demonstration boards exhibitions etc.

==========
Title : Camera Wireless Controller [# 034]
==========
Date : 960611
Author: David Kazdan
E-mail: dxk10@po.cwru.edu

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : E-mail author

Description :

My need was to put a Canon Rebel XS under radio remote control that
separated out the focus function (button half-press) and shutter
release (button full-press). Solution was to use off-the-shelf model
radio control equipment and a BASIC Stamp.

Stamp plugs into the R/C receiver and decodes one channel. Stamp
output is two transistors wired to a subminiature stereo plug which

plugs directly into the Canon. Many other cameras have similar
interfaces.

E-mail: ih@doc.ic.ac.uk

Stamp model : BS2-IC Module
Code available: N/A

Filename : N/A
URL : http://www.doc.ic.ac.uk/~ih/teaching/radclock.html

Description :

This student project was completed very successfully.

The objective was to program the BASIC Stamp II to continually
decode the data from a radio receiver tuned to the time signal
broadcast by the National Physical Laboratory in Rugby (UK).

The resulting time and date information was to be displayed and
updated on an LCD panel.

Check out the WWW page for more information.

==========
Title : Weather Station I [# 039]
==========
Date : 960701
Author: Christer Johansson
E-mail: cj@hth.com

Stamp model : BS1-IC Module
Code available: N/A
Filename : N/A
URL : Soon to come

Description :

This weather station is able to measure temperatures from -55 to 125
degree C, wind speeds from 0-50 m/s and wind directions from 0-360
degrees and sends the results via an RS-232 compatible interface to
a PC running a companion program written in Visual BASIC.

The VB program running on the PC polls the BASIC Stamp at regular
intervals and performs corrections and average calculations as well
as presentations and logging of the measured weather data.

==========
Title : Private Aid To Navigation [# 040]
==========
Date : 960701
Author: Bill Bohan
E-mail: wlb@why.net

Stamp model : BS1-IC Module
Code available: YES
Filename : N/A
URL : N/A

Description :

On inland lakes and intercoastal waterways the US Coast Guard may determine that a privately owned structure such as a Dock, Port, Breakwater, Barge, etc. may require visibility at night. The purpose being for Navigation, Safety, and Legal Liability.

I modelled my own PATON (Private Aid TO Navigation) after professionally made units. A remote, battery powered, solar recharged flashing light.

Whats adds to the complexity is that the Coast Guard may require a very irregular flashing pattern that may not be standardized by regular counting ICs.

Because of remote locations, lack of maintenance visits, multiple lamps with a lamp changer is necessary. This means that while only one lamp flashes the pattern, it is measured between flashes to verify the filament is good. If not, an alternate lamp is chosen.

At 5000+ hours per lamp, using Electric Vehicle deep cycle batteries and SOLAREX solar panels (12V @ 1A each), a very reliable system can be made for a few hundred $$. Professionally made PATONs are much less in substance and average $2000. for a very basic unit!

==========
Title : Stamp II in Space [# 041]
==========
Date : 960716
Author: Mel Torrie
E-mail: mel@gas.physics.usu.edu

Stamp model : BS2-IC Module
Code available: N/A
Filename : N/A
URL : N/A

Description :

The stamp was used in the control of a growth experiment on the last flight of the Space Shuttle Endeavor (May 19). The experiment was to

determine the feasability of growing food in outer space, i.e. not in a pressurized cabin.

The Stamp II turned on heaters and controlled motors and solenoids to water the experiment at the specified time. It then took temperature measurements of the growth chamber and surroundings through a Maxim serial 12-bit ADC and stored the data in the EEprom every half hour.

It also sampled the battery voltage and when a threshold was reached, it self-terminated. The Stamp performed as planned and we were able to download the data at the Kennedy Space Center through our terminal software.

Our experiment was part of a NASA program called the Get Away Special
which gives students the opportunity to gain hands-on experience with
the space program.

==========
Title : MAT32 long integer math routines [# 042]
==========
Date : 960726
Author: Francesco Bonomi
E-mail: f.bonomi@agora.stm.it

Stamp model : BS2-IC Module
Code available: YES
Filename : MAT32_06.BS2
URL : N/A

Description :

A set of binary long integer math routines, with the following
approximate timings (for 32-bit numbers):

addition 0.05 secs
subtraction 0.05 secs
multiply 0.1 secs
divide 4 secs <--- No, it's not a typo!

The routines work with numbers that are 24, 32, 40 or 48 bits long.
More than this, I run out of memory.

If you don't need multiplication and divide, you will have room for
up to 56 bits. Changes for a larger precision might include storing
the multiply buffer in EEPROM, this makes ense if you need to
multiply one variable number by a large, constant number.

Divide is terribly slow, but BTW, being a Stamp-Basic implementation
of a sort of floating point divide, you can esily change it to have
fractional (fixed-point?) results.

A set of BCD routines is also available, but no division!

==========
Title : Distinctive Ring Detector [# 043]
==========
Date : 960801
Author: J. Gary Sparks
E-mail: sparks@indy.net

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PULSIN2C.BAS
URL : N/A

Description :

The STAMP moniters the ringing of a telephone line which is "filtered" through a retriggerable monostable 74hct123. The STAMP determines whether a 2 second ring has occured (which is a normal ring) or a .8 second ring or a .4 second ring (which is an option available through most phone companies called "Distinctive Ring" or some other such name) has occured.

The STAMP then turns on a relay to connect a given device to the phone line. This allows one phone line to connect to several devices selectively without the addition. of a second line. Each ring pattern is rung by a different phone number, so different phone numbers can be routed to different devices

76. MFJ 1292 Video Digitizer

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-05 00:00:00 UTC
From: rekoss@ix.netcom.com
Message-ID: <4u3ngj$ic@dfw-ixnews8.ix.netcom.com>
Source record: 103556
Cross-posted to: rec.radio.amateur.digital,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I splurged at the Jacksonville Hamfest this weekend, and picked up a video digitizer, MFJ's "Picture Perfect" Model MFJ-1292. I installed the board and software (v3.2) and fired it up. Now comes the problem: The program seems to be working properly, and seems to be responding to the camcorder. At least it knows when the camcorder is "on" or "off". Unfortunately, when I try to capture the video, nothing happens. The program says it is capturing video, but nothing ever gets into RAM. I have checked the specs, and the camcorder output signal is just what the MFJ board is (supposedly) looking for. Suggestions or comments would be appreciated - please E-Mail to rekoss@ix.netcom.com, or to kossr@edl1.ksc.nasa.gov. Thanks !

Another thought -- just use IPHONE. Although it would be a 1-at-a-time
deal, it would be easy to do. FWIW, I've been talking to a group of
hams back in the USA via IPHONE and some control software called
REPEATER LINK. I can even access their repeater phone patch using a
midi DTMF simulator to place local calls to my folks. Of course, this is
not exactly private since the call goes over the repeater, but it sure beats
paying 3 bucks per minute for a quick phone call back to the states.

Talked with some other guys using CW via iphone....sure works better since
propagation is lousy.

Lots of neat applications using IPHONE....check them out.

78. ISO design ideas for 1 Watt 14 MHz sine generator

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-05 00:00:00 UTC
From: fgrieu@micronet.fr
Message-ID: <fgrieu-0508961012360001@news.micronet.fr>
Source record: 103558
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

I'm seeking design ideas for a 1 Watt 14 MHz sine generator
with the following specs :
- 1 Watt output into 50 Ohm load (20 V peak-peak)
- any harmonics 50 dB below 14 MHz fundamental
- 100 ppm frequency tolerance => start from a crystal
- no (or few) adjustment
- reasonable efficiency (60% ?) from 24V DC power supply

Thanks in advance for your ideas.

Francois Grieu - fgrieu@micronet.fr

The Maxim MAX038 is a good sine-wave generator, after it warms up! Your
10V amplitude signal will require a 900V/us slew rate opamp plus a
200mA, 900V/us slew rate driver. The ELANTEC EL2030 may be a good opamp
choice and the EL2008C and EL2009C buffers can both supply 1Amp
with over 2500V/us slew. These will provide a tunable source.

Or you may prefer a tuned gain and power output stage.

Hi Jack. Unfortunately, at only 80 khz separation, you'll need a _lot_ of horizontal separation...there will be desense (a boat load!) in your applications. I doubt if you can even find a tower tall enough to support vertical separation. They, being the newer kid on the block, need to move to the upper end of the band, maybe around 147.54ish (not being familiar with the digital plan in your area).

Another problem is equipment. You mentioned you're using a commercial rig (micor) for the node. You won't generate too much wide-band noise with your tx...but...if they're using a modern synthesized rig, they'll probably drive you nuts (even if they move to a distance where you don't bother them!) with their tx. I had a similar problem where a synthesized node was freaking out one of the repeaters I maintain. There aren't enough cavities on earth to clean up some synthesized tx's.

I think 100' horizontal separation might work if:

1- They also use a commercial TX,
2- They locate their TX as far as possible from you,
3- They move to the opposite end of the band,
4- You may still need 1 notch cavity on each system to notch out the other tx.

Just my $.02 based on similar experience.

As a side note, I maintain a 220 repeater site where a local VHF packet node is installed. The node is a conventional 2 meter synthesized rig. I had to install 1 2 meter notch cavity on the 220 repeater (!) to eliminate desense..whew...

73 es good luck!

Blanket statements like this are dangerous. Many commercial repeaters/
two way radio systems use CW ID. It's less disruptive of "traffic" than
a voice ID'er, and it is easy to automate to conform to the 10 minute
rule.

So there IS commercial usage of CW.

Could someone point towards info on how to broadcast on FM radio.
I've heard it called free radio or pirate radio. Does that mean it's
illegal (how illegal:)? What makes it illegal (in florida)? Where can I
buy the equipment? What would I need to buy? I just want to transmit 5
to 10 miles and just music (mostly my own and my friends music so as not
to violate copyrights or whatever).

Interesting point. You may be right. Still, it irritates me that FCC has
any questions on RF emissions and safety other than the usual "why
should you not hang onto an antenna when someone's transmitting a gallon
on it?". While at microsave frequencies and above (and, perhaps, at high
UHF), disastrous things can happen when humans get in the way of
high-powered RF fields, I am not at all certain (learned ptomes on this
newsgroup to the contrary notwithstanding) that RF emissions pose a
serious hazard at VHF and below. Certainly the Novice question-pool
question as to why one should keep the rubber duck antenna of a HT away
from one's head when transmitting seems to me not to be proper exam
material in that IMHO the jury is still out on RF problems at VHF and
below.

I know, at least, that I've used HTs with rubber ducks for over twenty
years and haven't noticed a thing other than the financial drain of buying
battery packs!

Hi,
has anyone any experience of protecting tubes agains flashovers, by using a thyratron to cut the HT off rapidly in the event of a flashover ? I've seen such a scheme mentioned in some Burle (formally RCA) application notes and are considering it. Suffice it to say, I think I can lay my hands on a thryatron cheaply - the leftovers of an old PhD project here.

I dont suppose I would bother if the tube is cheap/plentiful, but if one has an expensive tube that is pretty much irreplacable on cost grounds, this might be worth considering.

Yes indeed! Tune your receiver around 8600 kHz some evening. I found about 10-15 stations last night sending CW "idling" messages, and then a few actually sent text messages (fairly long) in CW (these were commercial messages, to ships I assume).

There aren't as many as there were 20 years ago, but some of the standards (WCC, WOO, CLN etc) seem to be still active on CW.

From: kjhales@aol.com
Message-ID: <4u7ph5$d3g@newsbf02.news.aol.com>
Source record: 103489

A digital guy wants to build an analog DC receiver and has the following questions:

1) Audio amplifiers
The best op-amps I have run across have about 0.5uV input noise in a 3KHz band when driven from 100 ohms. Can I reasonably expect to do better with a discrete design? Or are other limits in the system going make improvement useless?

2) Audio Phase shifters
I have seen two types of phase shifters. One is a massive wad of R and C with 2 inputs driven 180 deg. out of phase. The other is a 6-pole active filter with an op-amp per 2 poles. All examples I've seen fail to give the theoretical values for the components, but present values that have already been rounded off. Does anyone have details on how to calculate the values of R and C for a phase shifter? Or exact values for some of the published circuits? Are 8-pole circuits practical, or do the component tolerances get too tight? Most circuits are designed for 300Hz-3KHz; can this be stretched a bit (say, 200-4K)?

3) LO phase shifter
Suppose I have a LC oscillator. Can I tap 2 points on the inductor and get signals 90 deg. apart? Assuming tuning is done with the capacitor (L is fixed), will the phase shift be constant over freq?

In case you wonder why I want to do this, my day job is DSP and I am a heretic at heart. The reference materials I have on hand are the Handbooks from ARRL and RSGB.

Thanks for any help

Kevin Hales

Fully support Gary's point of view
Although I very much enjoy CW and hope some spectrum will always be
left for CW operation , wanting to maintain the code requirement as a
requisite for access to the HF bands ,while code is no longer used by
the non-amateur community , highlights a dinosaur atttitude for which
IMHO is no longer place in today's world . Afterall it's 1996 , no
longer 1956.
Let those who wish to operate CW enjoy it ,but let's not force it
upon people who are interested in other aspects of our common hobby.
Let's all move forward in a real world. As a bonus we then will
possibly be able to keep the spectrum currently allocated to the
amateur service.

>operator liable because he had knowledge of the EPA guidelines of RF radiation
>?.

You bet. The lawyers will love this. But you can be sure that the
manufacturer of the radio will be sued too. Remember the deep
pockets rule. General aviation was nearly ruined because the deep
pockets rule meant that the aircraft manufacturer was always sued
when some pilot did a stupid thing and hurt someone. The legal
theory was that the manufacturer should have built the plane so
that the pilot's stupidity couldn't cause an accident. Same logic
applies here.

>Also I wonder what the FCC intends to do with all the land mobile equipment
>as most all is 100 watts. The article implies a mobile station operating over
>50 watts could also not be in compliance with the guidelines..

Worse than that, Gary, the 50 watt exemption only applies to *amateurs*.
It does not apply to other classes of licensees. They've got to certify
compliance at *any* power level. Note that "push to talk" *radios* are
exempted from certification by their *manufacturers*, but *stations* using
such radios are not. The *licensee* is still responsible for seeing that
his station operates in compliance with 47 CFR 1.1307, 1.1311, and 1.1312.

However, Part 90 *portable* radio stations are categorically exempted.
I'm not sure the FCC considers "mobile" rigs to be "portable" radio
stations. If not, *each* installation must be certified. Otherwise,
they're exempt *regardless* of power level. Cops always seem to be
"more equal" under the law than you or me.

97. Need antenna solution for 1969 Vette

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-06 00:00:00 UTC
From: Dan Newby <newbyd@omniview.com>
Message-ID: <32077AD3.4F01@omniview.com>
Source record: 103493

I'm looking for an antenna solution for a 1969 Vette. Of course I don't want to drill any holes and an on the glass mount won't work on the rag top.

I've been thinking about putting an antenna in the factory hole for the am-fm antenna. I can put some aluminum tape on the inside of the body panel for a ground plane. But then the problem is I don't have an antenna for the stereo.
Has anyone seen any duplexers that would let me use one antenna for the ham bands and the bradcast stuff as well? If they made a low pass section that cuts off at 110mhz and a high pass at about 140mhz, it would be perfect.

Does anyone have any good ideas?

Thanks,
Dan Newby

To get a 90 deg phase shift over a wide freq range, the easiest way
is to have the LO at 4 times the desired freq. The LO output goes
to a flip/flop and divides the freq by 2. The two F/F outputs, Q and Q/
each got to another F/F. the Q outputs of the last two F/F's will be 90
degrees apart.

Before people go ballistic over this, let's get the facts. Can someone find out what these rules actually say about amateur stations, if anything? What does "MAY" have to perform an RF environmental assesment mean? Does this apply to sporadic transmissions like ham stations, or only constant emissions like broadcast, cellular, relay towers, etc. Are frequencies taken into account in any way (certain parts of the VHF, UHF, and microwave spectrum have much greater potential for biological impact than HF or other frequencies. Is there a certain distance from an antenna to the nearest house, etc. that would exempt most of us? Also, don't all proposed new rules have to go through a comment process?

There already are "environmental impact" rules about antenna structures, and 99.9% of hams just check a "No" box on Form 610 and get on with their lives.

I'm sure the ARRL, not to mention many commercial organizations, would raise quite a squawk if every user of a 50+ watt transmitter in the U.S. had to file Love Canal-style paperwork. This would involve every police and fire department in the country, for starters.

The "key" is in the name of the file: "HOMBRW.TXT."

If you "Extract" the file with your news reader program and save
it to your hard drive, you can double-click (from File Manager), or
view it under any of the Microsoft programs that work with .TXT files.
Trumpet News Reader will automatically display the .TXT file after
you have extracted it. It works the same way as when extracting and
viewing .JPG (and other specialized) files.

I doubt if there is much lead but the smoke is far from "healthy". Try placing a small fan to one side. A slight breeze is all that is needed to keep the smoke out of your face. You can even "whistle while you work" (blow gently) while you solder. If you do a lot of soldering you may wish to get a HEPA air filter or some ventilation for the room. More fancy approaches include vacuum pickup devices - either a whole-bench pickup similar to the hood on your stove or a little pipe at the tip of the iron with a vacuum system exhausting to the outside. We used the little pipe technique for several years and it works great but the vacuum pump is difficult to aquire and tended to get clogged with flux due to lots of users. You can find suitable constant-duty pumps in some larger computers or copiers at the local junk yard. They are used for forced-air cooling, in most cases. I also have a computer fan mounted in a Bud box with a vacuum cleaner hose. The fan "sucks" air into the box and out the hose. Just place the box near the back of your work and away go the fumes out the window (or hole in the wall, in my case)! Disregarding the health factors, such a system is still worth making for your general comfort level.

An EA filing would be required if a station is out of compliance with
the new exposure rules and wishes permission to operate anyway. Without
a complex, costly, and time consuming EA (and favorable FCC action,
frankly unlikely), an amateur station *must* be brought into compliance
with the new rules by Jan 1 1997.

This is likely to affect a considerable number of amateurs. I'd
suggest most amateurs running more than 50 watts who use an indoor
antenna are out of compliance. And those using low outdoor antennas
may have to install fences with access interlocks before being able
to crank the power back up over 50 watts.

OTOH, if your antenna is more than 10 meters above any horizontal
surface where a person might stand, and you're running no more
than 1,000 watts ERP (that's your output power minus feedline
loss and plus antenna gain), you're probably Ok. You'll need to

evaluate each situation, however, to be sure you are in compliance, this is only a very crude rule of thumb, and not sufficient to assure compliance (your MPE might still be too high in the above scenario depending on antenna type and orientation). The chart in Appendix B of the report and order gives the allowable limits for controlled and uncontolled exposures at various frequencies (exposure limits are different for different frequency ranges).

The controlled exposure numbers are the limits for *your* exposure. The uncontrolled exposure numbers (much lower) are the exposure limits for any member of the general public due to your transmissions. This latter number is likely to cause problems for those operating in apartments or condos. (The numbers are approximately 30 times lower than the previous ANSI limits the FCC has used in the past for licensees not exempted, IE broadcasters. Amateurs *were* exempted, but no more if they run 50 watts or more.)

If we follow the good amateur practices of mounting our antennas as high and in the clear as possible while running the minimum power necessary for communications, many of us will be Ok. The problems are going to arise for those using indoor antennas, low outdoor antennas in access uncontrolled areas, and for those with close neighbors or public throughfares. HF mobile operators are going to have to be particularly careful. Operating in a parking lot, or in heavy traffic, could easily put you out of compliance unless you drop your power to below 50 watts. There aren't many VHF+ mobile operators running more than 50 watts, so most of them will be exempt. Those who are running 50 watts or more, however, are going to have to take steps to limit exposures.

People running glass mount antennas are almost certainly out of compliance with even the controlled exposure limits, but remain exempted if they're running less than 50 watts. That's not a good reason to still be suffering excess exposures, however, and prudence would suggest getting rid of that glass mount and drilling that hole in the roof like I've been urging you to do for years.

Repeater owners may be in particular trouble if their site isn't controlled access (and even if it is if the *combined* exposure from all sources on the site exceed the controlled exposure limit). In the latter case, *everyone* will have to shut down any time maintenance at the site is to be performed (or suitable protective clothing will have to be worn by the maintenance personnel entering the area). This is a *biggie* folks, and may limit amateur access to many places where we've traditionally sited repeaters. The site owner is going to be held primarily responsible for seeing the exposure limits aren't exceeded, and they're going to turn a fish eye on amateurs trying to cadge a free site. (Get your "moon" suits now, it may be the only way you'll be allowed onto many sites.)

Note, we don't have to file an EA unless our station is out of
compliance and we want to operate it anyway. But we *do* need
to do the measurements or calculations showing that our station
is in compliance with the exposure limits if we run more than
50 watts. This information must be kept with our station records,
and be available for FCC inspection at any time.

Some of the limits are going to be hard to measure. For MPE, above
30 MHz there aren't any trustworthy instruments available. The
FCC is going to allow us to measure the Volt/meter field and
calculate the MPE from that. For well characterized antennas,
the FCC will also let us depend on computer simulation calculations.
For SAR limits, that's the only prudent way.

Hardware gurus need to be designing suitable instrumentation for
us to make sure we're in compliance (and suitable field calibration
techniques to assure us the instruments are trustworthy). Software
gurus need to give us computer programs to model exposures. Both
of these are going to be tough tasks if they're to work in the
real world where our stations operate, and not in some idealized
free space.

Remember, we have to have documentation on file with our station
records showing that we are in compliance before we can run 50
watts or more. 49.99 watts may wind up being the new defacto
amateur power limit if we can't come up with reliable hardware
and software to document that we're in compliance with the new
exposure limits.

To my thinking the real, immediate problem is that IF the amatuer station has to file an EIS, that gives every neighbor and enviro-busybody an invitation to object, delay and appeal the "construction" of the station. Out here on The Left Coast, that practically guarantees a group of hystericals and allies from The Birkenstock Brigade adding their 2 cents worth to every station they decide is a "risk". Remember how ham radio got pilloried by KING-TV, Channel 5 when the neighbors set on sacrosanct magnolia Hill had problems. I can't wait for that old rag Jean Ennerson to find this issue to crusade on.

> 73 de Jack

Jack,

There is no hard and fast rule since numerous variables are involved. Things like antenna gains, bearings and heights and feed line losses are important factors.

Assuming a conservative rejection of 70 dB at 80 KHz spacing for your receiver, -130 dBm useful sensitivity for your receiver and 36 dBm (5 watts) transmit output (and no feedline loss), then -135 + 70 - 36 = 96 db of isolation is required.

If the two antennas are half wave dipoles (0 dBd gain) at the same height, there would be 41 dB of isolation between them given 100 ft (15.2 wavelengths) separation on 2 meters. This is less than one-half the isolation required.

If the two antennas have more gain and are oriented (by height or bearing seperation) so that the two radiation patterns tend not to overlap the isolation will be increased. However, it is unlikely that the required additional (96 - 41 = 55 dB) isolation would be obtained in this way with certainty. It may *possibly* be obtained by painstaking location of either antenna so that the antennas are in each other's nulls in radiation patterns.

Of course, cavity filters could easily provide the required additional isolation.

NOT! OK, I admit it: I got carried away with the analog opamp-style parts! The -038 has 200 ppm/degC typ drift and is clearly unsuited for a 100ppm task, as Francois asked, wheras likely any old crystal will exceed that spec.

>10V amplitude signal will require a 900V/us slew rate opamp plus a
>200mA,... driver. ELANTEC EL2030 opamp ...and EL2008C /09C buffers...

Ditto. Only a tuned class-C conventional RF output stage has the potential to meet Francois' 60% efficiency goal! ;-)

CORRECTION
Contrary to our first reading, it does not appear likely
that any hams will be subjected to filing EIRs. Word to the wise:
Don't read government legal opinions while your 9 year old daughter is
holding a big birthday party with a crowd of 9 year olds :)

While the ruling does place additional rules and compliance
issues upon Amateur Radio stations, I'd guess that having a
federal standard will help to prevent lots of local
municipalities from creating their own, usually ill
considered regulations on RF emissions.

We corrected the web article shortly after posting on Usenet
(which you can retract once posted). Oh well.

Interesting play anyway Ed and Kim. I went to the FCC server and got down the whole 1 meg Word Perfect 5.1 file anyway. Haven't read it yead, but I will. It probably is close to the ANSI standard stuff that is already in the ARRL handbook and not a bad view of life anyway. Actually, if you look at the charts and do some real thinking, the curves and distances for you to use in plotting "safe" spacing between you and your antennae, they are not all that unreasonable. When laying out my more recent antenna arrays on low band stuff for the vertical arrays, I did the check runs for the space required by the new projected standards and my operating position.

What I found was interesting from a far different perspective! Considering that feed line lengths are part of the limiting factor on how far away you can afford to go to get to an antenna and the higher the frequency is, the shorter your pocket book gets, a curious thing happens.

There is so much interaction between vertical arrays and other vertical arrays that are higher than them then the whole business of how far away they have to be from the shack is somewhat moot! If you lay out a plant with anything like the right minimal spacing so that the bigger and taller arrays don't tear up the shorter higher frequency fellers, the spacing from the user is so far above the proposed new standards that they are, in effect, meaningless.

To keep a 160 meter vertical from tearing up an 80 meter 4 square array takes about 600 feet of lateral space separation.......

Plot it all out with MN or whatever.. You'll be surprised. It takes real work to figure out how to hold interaction down without spacing separations like that...

After having worked in the broadcast business as well as being a ham, I really don't want to put an indoor loop antenna in my appartment and then feed 2KW PEP into it, nor do I want to put a three element beam on a roof top rotator right above me in the attic and toss 2KW PEP into that either. Surely running the limit on RTTY that way must make it worse even by common sense.

The charrts that are there are interesting. Mobile unit field levels are also interesting when you take a look at what is happening there.

High power VHF stuff does present hazards...

For you to have simply gotten the attention of some people and perhaps piqued their interest in the issue, may have helped..

Oh knowledge of the affair isn't really required! Product liability, for example
transcends all reasonable sane limits for time elapsed on that, with or without

knowledge.

I am familiar with one lawsuit now going on where the product involved was built in 1978. The claim is the gate design on a cattle trailer was defective and the user had the gate come open last year and the cows fell out and caused a massive traffic accident.

Allegations seem to be that because the design was copied from another product back in 1963, it is really not the copiant that may have the final liability, but the party from which the design was COPIED!

For millions of dollars in claimed damages.....

:)

I do! Imagine if everyone voluntarily kept their output power limited to under 50W. Remember, we're supposed to run the minimal power necessary for reliable communication. Since folks don't self-police themselves in following this regulation, we'll now have the government carry out those duties. But we can thank the FCC for *raising* the cutoff to 50W; the original proposal was for a lower power level.

As long at that is 50W output and not 50W ERP, just think of the more efficient antennas that are going to be sprouting from each shack now.

>transmitters to id.
>All uplinks are required to do this.
>(commercial)

No. We're required to encode our call sign in the vertical blanking interval in such a way that rolling the sync bar down allows it to be read off the monitor. Or we can use a specified digital encoding in the vertical interval instead (this has become the most common method and is more adaptable to automatic computer control of networks of uplink systems). We *cannot* use OOK because that would change the transponder saturation level and would cause interference to other signals being relayed.

Commercial satellite transponders are operated with a specified saturation level. When we power up, the satellite control center will advise us to increase power until we reach the specified saturation level, and then hold it there so that we won't pump other signals using the transponder. (We watch that on the downlink spectrum analyzer in the truck anyway, but satellite control has the final word.)

We can't use MCW on one of the sound subcarriers for the legal reason that we must continously ID our uplink signal (so that a source of double illumination can be identified immediately), and for the practical reason that we're using the subcarriers for program audio anyway.

I'm not familiar with the ID requirements of SCPC or other data uplink systems, but they can't use OOK either, and I would opine that they embed their ID in the data framing (somewhat similar to amateur packet).

If you use a 12 volt car battery and your converter is 100% efficient, the current drain from the car battery will be 260-320 amps. (Actually it would be greater, because the battery voltage would be less than 12 volts under this kind of load and the converter wouldn't be 100% efficient.) The typical car battery would provide this kind of current for a few minutes at most. Running a car battery completely down just a few times will ruin it. A deep-cycle battery would withstand the deep discharges but probably wouldn't produce that sort of current at a reasonable terminal voltage.

That's quite a PA system you've got, consuming over 3500 watts. Not what I would call "small"! Surely you can find a 12-volt powered PA you can run directly from a battery, that doesn't require that kind of power.

If your DC rx is for HF and you'll be using reasonably efficient antennas,
atmospheric noise will typically limit the system if you use one of the
lower-noise op amps. Any further improvement in receiver noise figure
over this won't improve system performance.

I'll try to answer your questions based on my understanding of your post. First a question: Is the venue where you wish to perform either unequipped with electrical power or unwilling to allow you to plug into thier mains? If the answer to either question is yes, then some form of invertor is called for. From the power requirements that you specified, it sounds like you are either running a lot of equipment or are just anticipating worst case requirements.

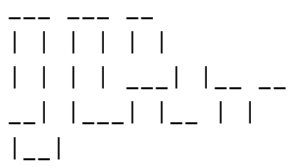
Invertors are off-the-shelf items. You can get these for US$100 for a 200 watt unit, a 500 watt unit goes for US$230. Larger units are available, but they are uneconomical. Tripp-Lite(tm) is a major U.S. maker of these units and I believe they are international. These are used in RV's (I think you call them caravans), and aboard yachts. They take 12v or 24v from a storage battery and produce a rough approximation of mains power. (see below)

If you are running a lot of equipment, get several invertors and batteries. This will help keep the costs reasonable, and provide redundancy in the event of failure. Don't overload them, the better ones are designed to shut down until the excess load is removed rather than blowing fuses and circuit breakers all over the place.

Each invertor should run from its own battery, for both practical and safety reasons. The minimum battery size should be around 50 ampere-hour, and I recommend using a deep-cycle battery, rather than a standard automotive starting battery. Although these are more

expensive at first cost, they are more economical in the long run because they are designed for multiple deep-discharge cycles, which would quickly ruin a standard automotive battery.

There are some caveats: Most invertors produce either square-wave output or "quasi-sine-wave" output. Many of them will usually say on the name plate what they produce.



Square wave Quasi sine wave

If whatever you are running does not have AC motors in it, you are OK. Most purely electronic equipment is tolerant of square wave power. If you are running anything with an AC motor, you will have to get a true sine wave invertor, which will be about twice the price of a suare-wave invertor.

for more information, go to

http://www.tripplite.com/ or
http://www.industry.net/sola.electric

Sorry, I can't help you with the lottery. <G>

I think there probably are some lead vapour and particles in the smoke,
but the resin fumes are probably more harmful. I read somewhere that one
can become sensitised to them, resulting in a form of asthma, in some
cases. Someone I know recommended blowing from the mouth over the joint
whilst soldering, ensuring that the fumes aren't breathed in, and are
blown away at the same time.

The handbook article is also incorrect in many ways. N6GN's web page
for the project has some of the corrections needed.
http://www.tapr.org/~n6gn/uwavelink/uwv.html

I have also noticed a few that are not on the page. As soon as I get them
together I post them so the page can be changed. The ones I remeber are that
the base of the LO JFET is not grounded on the board, and the LM386 amp is
connected correctly on the board but not the schematic. I know there is one
or two other missing connections, but I don't know them off the top of my
head (oddly enough :)

Uhh..you do realize that rainwater does not meet EPA regulations for discharge into public bodies of water? EPA rules say pH MUST be 6-8. The fact that absorbed carbon dioxide makes it pH 5.5 makes rainwater a violation of EPA regulations.

Also spring floods due to particulates. To say nothing of natural background radiation, mercury, lead, etc., in areas that have that stuff.

Subject: Direct Conv. Receiver Questions

3) LO phase shifter
Suppose I have a LC oscillator. Can I tap 2 points on the inductor
and get signals 90 deg. apart? Assuming tuning is done with the
capacitor (L is fixed), will the phase shift be constant over freq?

Probably not; in any case the amplitudes will not be equal.

A nice way to get a clean quadrature output relies on the fact that
doubly balanced mixers give zero DC output when fed two signals in
quadrature:

```
I ------|
|
Q------(X)---- LPF -- nothing (If really 90.000 degrees and mixer ideal)
^
DBM
```

When the inputs are not in perfect quadrature, an error signal (whose
sign depends on which signal leads in phase w.r.t. 90 deg) comes out at
DC, and you amplify that, and feed it to some varactors that are in your
phase shift network:

```
VFO------Splitter------ I output
|
|
----inductor----- Q output
phase | |
shift | |
network | |
--- --- /|
\/ varactors \/ / |
--- --- / -|----- from I/Q mixer LPF
-----------------------------/ |
--- --- \ |opamp
/\ /\ \ |
--- --- \+|-------- GND
| | \|
GND GND
```

(Add your choice of loop filter things... like freq. comp. for the
opamp, and a complementary phase-shift network with one varactor
through, and two inductors to ground, for "equal" signal treatment.)

This circuit has the advantage that it enforces quadraturity of the I and Q ports over however far the varactors can tune, to within the tolerance of the mixer's idea of "perfect quadrature" = no DC output.

***** Breaking News Story *****
FCC Ruling Prohibits Unreasonable Restrictions on TV Antennas
by Ham Radio Online, 7 August 1996

In a major ruling, the FCC declared void local laws prohibiting
or restricting the use of small wireless dish antennas.
More significantly, the FCC declared that use of small dish
antennas and television receiving antennas can not be restricted
by "any private covenant, homeowners' association rule or similar
restriction on property within the exclusive use or control of
the antenna user". Under the federal pre-emption, all homeowners
must be allowed to install TV antennas. Longer term this ruling may
have important ramifications for eliminating restrictions on Amateur
Radio antennas.

The complete story is available at Ham Radio Online at:
http://206.13.40.11/
(we are waiting for InterNIC to get our domain name pointed at our new
server).

>_____________________
>robert mailto:nix@gate.net

Ramsey sells a nice little kit that will broacast stereo FM at the legal limit for about 30 to 40 bucks. This won't reach the 5 to 10 mile mark you want, but will cover a block or two if you have good antennas and choose a part of the band that is relitivly unused in your area.

You could add an amplifier, but that would be illegal. There are large fines if someone has been complaining, which the big boys will do.

By "your own music", I assume you mean music that you and your friends have written and performed. Anything else would be a copyright infringement. I doubt you would have much trouble unless you started selling advertising. (Then EVERYBODY would be on your butt!)

If you keep the power at or below the legal limit, you can probably do just about anything you want. The signal won't get far enough to get you in trouble.

Source record: 103516

I don't know if this is the correct newsgroup for my question but I thought I'd give it a try. Basically what I'm after is any info on the feasibility/availability of a battery powered generator that could supply 240V at around 13/16A. It would be used to drive a small mobile P.A. system in environments where standard fuel based units would not be allowable (i.e.. indoor shopping centres). Someone has said that it should be possible using a car battery, a step up transformer, an inverter and some kind of frequency filtering. Is this so and can they be bought of the shelf ?
Any info on this subject would be greatly appreciated - I am working with a trained electrician but he has never had experience of such a unit so I'm trying to put out as many feelers as possible.
Thanks for your time.

Nick Sagar

P.S. Any formulas for winning the lottery would also be appreciated :-)

I would imagine so if your job was to sit there all day and assemble
or rework PC boards. It is objectionable as hell, sorta like someone
blowing cigarette smoke in your face while you are eating. Get any
kind of small fan (like a muffin fan) and arrange it to blow across
your work area. I use a 12v fan out of an old PC power supply, and
run it on 5v. It is quiet and the airflow is such that the fumes are
blown away, but the soldering iron is not cooled off by the airflow.

Hope this helps.

: OTOH, if your antenna is more than 10 meters above any horizontal
: surface where a person might stand, and you're running no more
: than 1,000 watts ERP (that's your output power minus feedline
: loss and plus antenna gain), you're probably Ok. You'll need to

This is a bit misleading Gary. It should be output power, minus feeline losses, multiplied by the antenna gain. For example, 150 watts out of transmitter, minus 10 watts feedline loss, is 140 watts at the antenna. If the antenna has 10 dB gain, then the ERP would be 140 times 10 or 1400 watts - which is too much.

So much for encouraging better antennas, rather than high power linears. There is now little reason to use an efficient antenna - as the penalty is the same either way. It is much easier to install a linear than a good antenna system.

Of course, you could limit the power under 50 watts, and install a very good antenna. However, I wonder if you would have to have a station that was incapable of greater power output?

I suspect that the new directive is only going to make a bunch of Hams lawbreakers.

Bill

It might be the manufacturers will have to apply a warning label on equipment to remind the installer / user of the possiable electromagnetic radiation problems of improperly installed equipment.

Kind of like warning label " Danger the coffee in the cup is hot and may cause burns if spilled upon yourself "

We will all learn about the EPA requirements for radio transmission and radiated power. I know manufacturers cannot build a handheld that transmits over 7 watts RF power with out going through MAJOR EPA loops and hoops. No body wants to go through all of what the EPA requires for handheld over 7 watts in power, so they do not build them.

I would guess this might also be a good case for antenna heighth. The higher the radiating element the less signal affects the immediate surrounding area

Ed,

The article on your web site " The following is the text of the FCC 96-396 R/O. Was that straight from the FCC or your interpetation of what the FCC was saying ?

I do not think just not having to file a EIR is a victory or sigh of relif, but the intemt of the FCC to require and make the amateur responsiable for proper knowledge and proper installiation / operation of his equipment . This would include his being resopnsible for not exceeding the EPA guidelines for RF exposure limits.

By mere addition of these questions on a test, you are made aware that the government assumes you know about these limits They would most likely hold the licensee responsible for operation with in the EPA RF Exposure limits. This could turn out to be be a major turning point in Amateur Radio.

Recently in Seattle, Wa area some brought a cellular phone company into court to keep a tower out of the neighborhood, although they group lost, still the legal battle was on. I for one will keep a weary eye to the FCC and EPA about my Amateur Radio operations, also will have another look at my station installiation.

I agree with comments re antenna siting. Vertical separation appears to be important.
However I doubt that even a shunt connected cavity filter would provide much attenuation at only 80 KHz away without attenuating the wanted signal considerably

Also watch for intermodulation products when both transmitters are operating. Signal from one gets into the other via a retrograde path and IM products are generated. This can be prevented by using an isolator in the feedline of both transmitters
We have seen this effect in Australia where multiple pager transmitters operating in the 148-150 MHz band are colocated on the same tower. They have a typical ERP of 1 KW. Spurious products fall the amateur 2 metre band.

Thirdly the phase noise sidebands of such a close signal would probably be audible in the other receiver, even for a good quality transmitter

I have a front projection Mitsubishi 50" color TV circa 1982. It has performed flawlessly for 14 years. Recently, the red CRT gun went bad. So I called several service facilities and Mitsubishi as well. I learned that a replacement gun is no longer available. So I bit the bullet and bought a new TV.

I'm still interested in fixing the thing myself, so I thought maybe I could leverage the Internet to locate a used, but operable CRT gun. If I can't locate one, I'm willing to sell parts off my TV to others in need.

I really didn't have a clue what newsgroup would be appropriate for my posting. Since I hold an advanced ham ticket, I have been reading this newsgroup occasionally. I asking if there is a newsgroup for my type of request, or if any of you homebrew enthusiasts might know of a TV service facitility that might have the CRT gun I'm looking for.

evil is in >>the details and the details say that if you transmit over 50 watts, you >>may have to perform an RF emissions environme=
ntal assessment of your >>Amateur station. Under the new rules, the FCC will add five more >>questions on RF safety to three of the =
written exams. Amateur radio >>operators will be required to certify as part of their license >>application, under an as yet unspeci=
fied mechanism, that
>>they understand the FCC rules on this issue. In some situations, >>certain Amateurs may have to file a complex "Environmental Asse=
ssment" >>better known as an Environmental Impact Report regarding their Amateur >>station operation.

In essence, the FCC is relying on the demonstrated technical ability
and proven self-policing track record and allowing amateurs to perform
their own evaluations. If we determine that our stations are in
comliance with current FCC regulations, we need not file anything with
the FCC. The FCC goes on to say that stations that run less than 50 watts
do not need to perform the self-evaluation but are presumed to be in
compliance.

The VAST majority of amateur stations are already in compliance with
these rules. Those few stations who determine that they are *not* in
compliance are expected to correct the situation or to file the EA as
described in Part 1 of the FCC rules.

The FCC then goes on to say, "We want the licensees of such stations to
provide adequately for RF safety. We do not believe, however, that a
detailed EA or other routine environmental filing is practical or
necessary. . . An EA would be evaluated by the Commission to determine
whether the authorization should be granted in view of the environmental
impact. In reality, this leads to a de facto compliance requirement,
since most applicants and licensees who are not categorically excluded
(see above) undertake measures to ensure compliance before submitting an
application in order to avoid the preparation of a costly and
time-consuming EA. For this reason EAs are rarely filed with the
Commission. This has not changed from the existing rules. "

>This could get real interesting. Since the article says the station >location and all occupants are in a controlled enviroment. T=
hey >consider neighbors and such to be uncontrolled. I wonder what will >happen if a neoghbor comes down with some mysterious illne=
ss like cancer >and notices he has been bombarded with electromagnetic radiation from >your station all these years could he hold th=
e operator liable because >he had knowledge of the EPA guidelines of RF radiation?.

This could happen right now, before these regulations are in place. A few hams have been sued, and a few local regulations were attempted, on these grounds. In those cases, most hams have NOT had an easy way to demonstrate that their station did not exceed the limits specified in recognized standards. Nor did those standards have the force of law. With the new FCC regulations, and the upcoming material being prepared by the FCC, hams will have regulations that limit the amount of energy they can radiate into their neighbors homes (IMHO, with a presumption that anything less than the allowed maximum is presumed to be safe), and, more importantly, a tool that will allow them to demonstrate that they are in compliance with the regulations, using OST Document 65 (being revised to OET Document 65) referenced many times in the Report and Order. I have to suspect that we will be better off this way.

>Also I wonder what the FCC intends to do with all the land mobile >equipment as most all is 100 watts. The article implies a mobil=
e >station operating over 50 watts could also not be in compliance with the >guidelines..

The FCC covered that in paragraph 67:

" 67. Although our exposure criteria will apply to portable and mobile devices in general, at this time routine evaluation for compliance will not be required of devices such as "push-to-talk" portable radios and "push to talk" mobile radios used in taxicabs, business, police and fire vehicles and used by amateur radio operators. These transmitting devices will be excluded from routine evaluation because their duty factors (percentage of time during use when the device is transmitting) are generally low and, for mobile radios, because the antennas are normally mounted on the body of a vehicle which provide some shielding and separation from the user. This significantly reduces the likelihood of human exposure in excess of the RF safety guidelines due to emissions from these transmitters. Duty factors associated with transmitting devices that are not "push-to-talk," such as transportable cellular telephones ("bag" phones) or cellular telephones that use vehicle-mounted antennas, would be generally higher, and we will require that these devices be subject to routine evaluation for compliance with general population/uncontrolled MPE limits. Although we are not requiring routine evaluation of all portable and mobile devices, under Sections 1.1307(c) and 1.1307(d) of the FCC's Rules, 47 CFR 1.1307(c) and (d), the Commission reserves the right to require evaluation for environmental significance of any device (in this case with respect to SAR or compliance with MPE limits)."

Now, back to writing the detailed report that my boss is making me write.

>
They call it PIRATE RADIO because they hang Pirates when they catch them.
That is what the FCC will do if you are caught broadcasting music 5-10
miles on FM Radio without a license. Amateur radio regulations prohibitthe
broadcast of music. Other broadcast of music requires a commercial
broadcast license. You are facing fines ranging from $2000 to $15000 if
you are caught, which means free radio is only free until you are caught.
These are serious fines, the FCC does noto mess around with parking ticket
size penalties. If you choose to use amateur radio FM equipment, licensed
amateurs will quickly track you down and report you to the FCC. Tracking
illegal stations is an Amateur radio hobby/sport.

I have a unit that has an activated charcoal filter in it that removes the smoke. Works good for what I need. Can't remember what company I got it through, but the brand name is HAK O 493 E.S.D. Smoker absorber.

It is nothing more than a large muffin fan with a filter on the front. The filters can be replaced.

This is not entirely correct. Videocipher encoded video on
satellite does use MCW on the audio subcarrier since VBI encoding

could only be seen by receivers with key authorization for that particular service. The FCC needed some way to ID the uplink on encoded channels without actually having to subscribe to the service.

>Is there lead in the smoke?

There shouldn't be any lead vapor in the smoke. Soldering temperatures
are well below the vaporization point of lead. There will be rosin fumes,
however, and they can irritate the eyes and lungs. Use a fan to keep the
fumes out of your face. I keep an ordinary 12 volt boxer fan on the
bench for this. There are commercial fume extractors available, but
the simple fan is usually sufficient.

The big lead danger is that some will rub off on your fingers while
you are handling the solder. This can then be ingested if you eat,
drink, smoke, or otherwise touch body openings without washing your
hands carefully first. Don't rub your eyes either. Obviously, don't
pull the old stunt of holding the solder in your mouth while you work.

You can also look at a LM567 tone decoder / phase lock loop. Look in the data
books. There is a sample circuit that lists "Oscillator with Quadrature
Output" Where there is a 90 degree phase shift. Being a PLL the freq. should
be pretty stable. Good to ~ 50 Mhz.

General Radio 1362 UHF Oscillator, 220-920mhz and
General Radio 1208B VHF Oscillator, 65-500mhz

I found these neat UHF and VHF oscillators at a hamfest for $5. Only problem is that they have a pigtail cable apparantly plug into a mating power supply, which I do not have. Does anyone know the pinouts or have a schematic? Perhaps even the supply? :)

Thanks and 73!

Does anyone know off hand if they are using the IEEE C92.1 limits? If so, Anybody trying to transmit at the normal 100W in a residential neighborhood (ie, low wire dipole antenna) may be in trouble. Forget about using attic antennas. The standard penalizes efficient antennas. I also believe the limits vary wiith frequency; I know that that the allowable ERP at 800MHz is only about 0.4W, compared to the previous 7W Max. transmitter power (the old standard did not consider antenna efficiency). I also know that 800MHz products designed well below the 7W transmitter power level usually did not meet the 0.4W ERP or that other parameter, SAR (for products held close to the ear). Yes, our handheld devices may be exempted but my point is that, if FCC is using the 1992 IEEE standard, amateurs in residential areas (a large portion of the ham population) will at the very least be marginal at 100W, if they use wire dipoles, G5RV's, slopers etc., and I believe the small 600W linears will be out of the question. I hate to sound like I'm sounding a false alarm but I'm not ready yet to buy into ARRL's contention (D. Sumner) that the new regulation will show how safe amateur installations really are. I'm sure he has a high tower to take advantage of 1/R**2. The new IEEE limits are much lower than the previous standard, but we will not start seeing this until after we start making the measurements.

It is worth pointing out that the FCC standards are from the NCRP and they represent a total exposure over a six minute period. As long as you are running HF sideband (or heaven forbid --even morse) your duty cycle is such that you will not be likely to get a continuous six minute exposure.

Remember that a sideband signal's average power is typically 1/4 of the PEP and that unless you are quite chatty (the FCC thinks we'll transmit and receive 50% of the time) you are unlikely to hit the limits of your exposure at 100 watts. So my Kenwood TS-50 will likely still meet the standards set by the FCC even though I typically run 100 watts. As for how I'm supposed to document this and where I'm supposed to file this report --that has yet to be determined.

I'm planning to build a detector for bats (the flying mammals!) probably for dumping into a laptop for some kind of spectral analysis. Anyone have recommendations for ultrasonic sensors? Different bat species use different frequencies, typically 40 kHz to 60 kHz, audio.

BTW, I've seen some standalone commercial detectors for about $250 but it's no fun just buying one!

Thanks, Tom KG6YJ

Having been a ham for 20 or so years, wearing a ham HT on my belt for a good portion of that time, and wearing a commercial HT on my belt during working hours for several years, and for the last 6 months undergoing chemotherapy due to lymphoma (which is, interestingly, cancer of the lymph nodes located in my abdomin, near where the HT antennas were located), I don't think I'll get too excited if I have to document compliance with a regulation designed to lengthen my life.

Cancer isn't any fun.

Sure, I know I'll get flamed, because I don't _know_ that the cancer was caused by the HT's, but then again, I don't _know_ that thay _didn't_ cause it.

John I feel you are correct in your opinion. The problem regarding CW is that the people who never learned the art of CW are the ones pushing to have it removed so they can have more room for voice communications. And for the most part could care less if many amateurs truly enjoy CW. If they cared about the CW operators they would get off their high horse and quit talking about how useless it is. It seems as if your a CW operator who tries to defend the use of CW they (NO CODE)get quite upset about it a then all of a sudden its you who has the attitude.

>think has faded away. Another one is on the fringe of my memory bank but

Haltek is actually on Linda Vista; from Amphitheater Parkway you must
turn south onto Terra Bella, then make the first left onto Linda Vista.

Also try Weird Stuff in Sunnyvale on Lawrence Expressway; it is associated
with Haltek.

While you are there you may as well go next door to Fry's. It isn't surplus
but many people will find it an interesting *grocery* store that sells
electronics.

There is a Ham Radio Outlet across Lawrence Expressway from Weird Stuff.

Then go to Halted Specialties (HSC) on Ryder.
From WS go south to Kiefer and turn left.
Turn left on Gordon Ave (first left) and turn right at the Y.

Since you will be in the area you should go to Alltronics 2300 Zanker Rd
in San Jose.

There *are* others: Jameco in Belmont, JDR in San Jose, etc.
but J and H Outlet in San Carlos is gone.

Come to think of it, you will need more than a week. :-)

Frank, do you really believe if CW was no longer required on the HF
bands that the NO Code Hams would not want your old useless CW portion
of the band for voice Communication. If you do than be prepared to throw
away your key forever. I like CW too all the more reason to keep it
alive.

Source record: 103462

Radio Shack ProbeScope, A Quick Review

The long awaited ProbeScope has finally arrived, so I rushed right down and=
bought one.
The software has a fatal flaw (for me). On my monochrome laptop, you can't=
see the acquired trace.
On a color monitor, the color mapping looks kinda like a green trace on a g=
reen background, but on the laptop =

gray-scale LCD display, the acquired trace is very dim against a very dim b=
ackground. It=92s not just low =

contrast, it=92s no contrast. I'd be interested to know if this is a quirk=
of the color mapping in my laptop, =

or if this is a universal problem.
The RS technical people had not heard of the problem.

Since I was going to take it back, I made no quantitative measurements. Th=
e following is only a quick =

overview of my observations.

It's a neat toy.
Specs are non-existent. The spec says that typically it may work. How wel=
l it works is anybody's guess.
The onboard LCD display is cute, but next to useless. Resolution is 16x32 =
pixels. You can't see much.
When hooked to a computer, the resolution is a more usable 64x128 pixels. =
You might actually do some real =

work with the computer display.

Vertical:
There are three vertical scales, 1V, 10V, 100V full scale. You can set zer=
o anywhere in the range so you can =

get the full range either positive or negative. If you=92re looking at a 3=
V TTL display, you have about 20 =

pixels to work with. You=92re not going to learn much more than if a signa=
l is there. On the built-in display, =

you get about 5 pixels.

With a low impedance source, the square wave response is quite flat on the =
1V range. The 10V range had about =

10% underpeaked response. I didn't have a flat source handy to check the 1=
00V range properly, but it looked =

about the same as the 10V range.

Horizontal:
The sample rate ranges from 50ns to 1ms. Good range, but the 128 sample me=
mory is just not enough.

Trigger:
The trigger is adjustable in six steps and worked quite well. There is no =
pretrigger view and no delay =

function. The autotrigger mode is actually a free-run mode. There is no t=
rigger in this function.

DVM:
The DVM reads in steps of 1/64V, 10/64V and 100/64V. So, if you want to me=
asure 12V, you have to use the 100V =

range and you get about 2V resolution. With a little practice, you can ge=
t that much resolution out of a =

light bulb.

Power Supply:
It will run off a 9V battery. Takes about 12ma with the backlight off and =
80ma with it on. Absolute max is =

13V, so don=92t plan on running it off a car battery with the engine runnin=
g. The manual describes a battery =

pack accessory that has 15 minute run time.

Computer interface:
The unit is not programmable. It acquires the signal and blindly shoves it=
out the RS232 port at 19.2Kbaud. =

I made a quick attempt to write a simple quickbasic program to acquire the =
data and solve my screen problem. =

19.2K was just too fast for Basic on my 386 laptop.

Documentation:
No documentation is available except what comes with the unit.

Subjective Stuff:
I tried looking at the vertical sync signal out of a VGA card. You can tri=
gger and look at the pulse width, =

but you can't measure the period. The relationship between period and puls=
e width are such that if you =

trigger on one pulse, you're guaranteed to miss the next one. 128 samples =
is just too coarse to look at this =

signal.

After the =93wow what a neat toy=94 factor wore off, I tried to list all th=
e places I=92d actually be able to use =

it. For troubleshooting computers in the field, it=92s too slow for the fa=
st stuff and the record length is too =

short for the slow stuff. You might look at line transients, except that 1=
20VAC exceeds the max input =

voltage. The vertical resolution is too coarse to make any useful quantita=
tive measurements.
My list ended up with no elements. If it had worked with my laptop, I prob=
ably would have kept it anyway as a =

toy.

Recommendation:
It=92s an impressive toy. If you have $100 burning a hole in your pocket a=
nd want a neat toy, here=92s your =

chance. If you don=92t have a scope and want one, go buy a used scope. Th=
e $10 fleamarket scope will serve you =

better in general use. I=92m going to wait for the next generation.

197. fft ANALYZER INFO NEEDED

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-08 00:00:00 UTC
From: viny Coppola <76103.723@CompuServe.COM>
Message-ID: <4ucq9ppeo3@mhafc.production.compuserve.com>
Source record: 103465

Need an FFT analyzer program that runs on a PC/soundcard that will not average and entire waveform, but allow the observance of the spectra of a part of the waveform. Does anybody know if such software exists as shareware or commercially ?

Thanks beforehand

Viny Coppola N1VC

I don't have a manual handy, but as someone who designed a few parts
of it, and then the special 90MHz version, I've still got a lot of it in
my head :-)

Can I help?

We no longer get a notesfeed to this site, so I now only rarely get
access to the groups via a remote login. Please try email to:

david_stockton@hp.com

If this doesn't work, my home address should be correct in all
callbooks.

Few microseconds depending on the type. I think 60 or 80 microseconds
is the upper limit for such devices, if I remember well.

Hello everyone,

I wonder if someone can help me, I have a Yaesu FT-290R1 that is doing
a great job on ssb. I would like a bit more power (it only runs 2.5 w PEP)
and as I like building I wonder if there is a circuit available for
an amp that will work with only 2.5w input and run 50+ w out.

Any information and pointers will be great (Remember I live in Dark Africa
and parts is not always easy to get !)

Thanks,

73, Rudi de ZR6VE.

Hi Duane,

Discussions like this tend to move to flames. I'll take my chance and exit if flames erupt. I regard flamers as dwelling in the depth of ignorance. Will not respond to any.

CW is not gone from non-amateur services and is not used solely for repeater IDs, either. Actual messages are sent and received daily using cw. It appears that will be the case for a long time to come. People who would deny this have only to tune across the spectrum. So... CW isn't really dead.

I held my extra class ticket all during the the no-code modifications to our rules. There were hot discussions about all the "dingbats" who would invade the ham bands. It was believed that cw was an infallible dingbat filter, keeping undesirable people out. I had to point out all those articles about FCC actions against jammers and other ne'er do wells in the ham ranks. Almost all of them were.... extra class licensees!! It seems the cw filter didn't actually work, either.

I *KNOW* we have more yoyo's with ham licenses, but there are also many more hams. Probably about the same percentage of dingbats as always. I have observed many new no-code licensees take the initiative to learn the code so they could have more priveleges (nobody has "rights") and many who were happy to live on the FM repeaters forever. Most are good people.

So... why should those who want more priveleges be required to learn CW? I had to learn about building and operating satellites (not just using them) and how to build and operate a repeater and other things that I intend *NEVER* to do when I wanted to upgrade to Extra. I have no complaint. I had to demonstrate knowledge of things I never intend to do as part of the "package" of priveleges I wanted. It didn't hurt a bit. Those techniques (satllites and repeaters) are current, but, as we have seen, so is CW. If you're happy with no-code priveleges (nobody has rights) then I'll see you on the repeaters. If you want more priveleges, then buckle down, meet the requirements (more than just CW) and I'll see you in even more places.

There are as many varied interests in ham radio as there are hams. I'd never "waste my time" linking a lot of FM repeaters to increase the coverage area. But... I think it is a cool idea and applaud those who do it. I'd also defend their "privelege" to do so. I might even use the system some time. Enjoy your priveleges. Earn more if you want them. Take some time to appreciate what all those other cool people are doing. You'll get even more pleasure from the hobby.

You can use the schematics of a lower power amplifier and you have to adapt
the components. There is no fundamental difference to ampliers using a
4-125A or a 4-400A or such a tube. Note that you can use the 4-1000A
in GG mode too, although it is probably not the best tube for this mode.
Considering that this tube is often available at a good price, this can
even be a good reason to use it.

I am currently a Tech+ ham licensed as N9ZLI. Just to save you the time, I'll tell you that I live Jeffersonville, IN just about 4 miles north of Louisville KY. Okay, here's what I am looking for:

Wanted, person or persons to assist newly interested ham in building small projects where cost is a major concern. I a looking for someone in the Louisville Metropolitan Area who is willing to sit down once a week (maybe more if time allows) and teach me about radio and how to construct my own goodies. I am currently stuck on 10m as my 2m radio was stolen. If anyone knows a good source for simple kits that would help me learn this wonderful craft, I'd be more than thankful. As I said, money is the biggest limitting factor to my enjoying amateur radio.

Thanks,
Misto
Joe Denison

Hi!

I just got my Tech Plus ticket a few weeks ago, but I don't have a rig!

I won't need my hand held too tightly (I'm an electrical engineer who's been interested in radio since I got my Novice ticket at 12 years old), but I'd rather start with a proven design than strike out on my own for my first homebrew rig.

I'd like to build a CW transceiver as SIMPLY and CHEAPLY as possible. QRP is fine. Any band is fine (I'll be getting my General ticket soon). I would kind of like to keep it in one piece but if separate transmitter and receiver would be better for some reason, I'm open to that too.

Pointers to circuits described in magazines would be nice, as long as they're accompanied by at least a short description of the project and how much it's likely to cost me in parts. Kits might be okay too, if they're really inexpensive.

Some ham catalogs came in the mail and struck price-shock into Bonnie, my wife. If I can show her that a homebrew rig built out of cheap parts and/or salvaged junk is all I require, her relief would be immeasurable.

Any help would be much appreciated...

There's no reason I can think of that the old Heathkit QF-1 wouldn't work; it's just not as "sanitary" an installation as that afforded by the Waters built in unit. The QF-1 has a flexibility advantage (selectable null, peak, etc) over the Waters, however. Waters manufactured a lot of nice accessories for the Collins line; unfortunately one of their competitors virtually 'stole' some of their ideas and began marketing ersatz products.

Depends on the diode and the forward and reverse currents. It can
be well under a microsecond for some diodes. Seems to me there is an
application note that covers things like this in the HP Microwave
and RF Designer's Catalog.

At my job I work with solder wafting up into my face all day.
I did as the others have done, put a small fan to one side to
blow the fumes away. A while back the company had some
guys come in a do air tests, they said there isn't enough
stuff in the air to be harmful, just be sure to wash your hands
before eating if you've been handling solder, and for God's sake
don't hold it in your mouth (as one of our less brilliant techs did
when both his hands were full).

Here in the US, all manufacturers of materials that may cause some health problems are required to issue a Material Safety Data Sheet (MSD). You can request it from wherever you purchased the solder, Radio Shack has them, other retailers may not have them but can get them quickly.
The information is very terse, but ventilation and exposure limits are very clear.

> presumably for the microwave board but isn't on the
> schematic
>
> There might be more; I haven't checked everything yet...

These all seem to be issues specific with that particular (older) ARRL
layout.

(1) both devices are the same 2n2222 so it doesn't matter anyway
(2) schematic is correct
(3) dual opamps in the same package. Doesn't matter.
(4) I think this was changed at the ARRL when they (re)laid the board.
the schematic in my 1991 Handbook shows things OK, as far as I
can tell.
(5) It's labeled U8 on the schematic I have.
(6) It appears to be shown correctly in the Handbook schematic.
(7) The ARRL layour used a different connector type but on the one
set of their boards I loaded, both the rx and uwave ends are working

with a ribbon (soldered, not connectored) between them) I think this
was done because they didn't have the connectors I used available.

Perhaps someone who has assembled a transceiver using the FAR Circuit
board set can comment. I have never even seen any board sets except
the early ones from the ARRL. The original four transceivers I built
were all hand wired. I did load and test the ARRL board set though and
it worked, with a couple of corrections. I believe that the corrected
schematic (corrections as listed on the web page) is suitable for making
all necessary corrections to the Handbook schematic. If this is not the
case, I'd appreciate hearing about it.

Thanks for taking time to list these, I don't know if anyone else is
presently trying to use the layouts to build their own boards. Perhaps
they can comment on any other corrections to that artwork.
If more are found, please indicate and I'll put them where everyone can
see them.

Has anyone had recent experience with the FAR boards or other layouts?

I did this to my FT757 GX-I so I could use the narrow CW filter
for RTTY without having to flip the tones in the TU. It involved
bringing out 3 wires to a toggle switch (I just let the toggle
switch hang on the end of the wires; I will leave it to your
imagination how to mechanically mount the switch.) The wires went
to the switching diodes that select the filters. It was fairly
straightforward to figure out from the schematic how to do this
I routed the wires out the back thru the left hand most ventilation hole.
I would guess that if you get a correct GXII schematic, you can
figure it out fairly easily if its anything like the original
model.

I looked around for sendors for the same reason about a year ago. About
the best reasonable priced devices I could find are the ultrasonic
emitter/detectors used for motion detectors. I have seen them in a
number of surplus stores that have ads in hobby magazines. The only
problem is that these have a somewhat limited frequency response.
Ideally, I would have wanted something that was reasonably flat from
20KHz to 80KHz or so.

The plan was to use a balanced modulator like the LM1496 to translate
the ultrasonics down to the range of human hearing and drive a pair
of headphones. Just one of those projects I never got around to.

Good Luck

Are there any microwave experts out here? This is not quite a ham radio question, but I figured that there must be someone here who can help me.

I need some ideas for a method to couple microwave energy, from say a MW oven magnetron, to a small liquid sample (a few cc's) which is mostly water. I wish to cause rapid heating of samples in a very short amount of time, with short microwave pulses.

I learned lots of this stuff in collage, but am really so far from it now, that I need one of you guys to point me in the right direction.

I apologize for the off topic post, and will gladly move off to email, so as not to drive everyone nuts. Thanks for your help.

: going make improvement useless?

Discrete parts can do much better than this, but then so can op amps.
There are several op amps with voltage noise levels around 1nV/rtHz or
below. The Analog Devices AD797 is one example, and it also is very
low distortion. At that noise level, the RMS noise output will be
dominated by the noise in the 100 ohm resistor, a bit more than 1nV/rtHz
at room temperature, and construction technique will become important.
Use low noise power supplies, a good layout, and appropriate shielding.

There are 3 dangers to soldering...
1) Being burnt!
2) Melting solder with an iron temperature above 800-850 degrees F (depending on tin/lead ratio), will cause the lead to be liberated in gaseous form. Not healthy to breathe!
3) Handling solder, then touching food that you eat. This will transfer lead from the solder to your fingers then on to your food... resulting in the direct ingestion of lead.

Ten years ago or so, I bought a set of "quadraphonic" headphones
on a close-out from a surplus electronics catalog. I don't know how
much they would have cost originally, but they were pretty cheap as
a close-out.

Anyway, it was my intent to wire them for four (4) different inputs.
But, as so often happens, I never got around to the project. They
are around here somewhere, and perhaps someday I *will*!?! :-)

Seriously (more or less), one pretty easy way to keep up with
three audio sources is to split the inputs to a pair of "open air"
(walk-man) type headphones. That gives you two inputs, and you can
still listen to a third source in the background via a loudspeaker.
I've done it.

Hey, life is short... I believe in "multi-tasking". :-)

Has anyone out there built the Roanoke Doppler DF unit described in "Transmitter Hunting ..etc." by J Moell and T Curlee ? If so, can they confirm that there are no errors in the schematic diagram (Fig 9-5) , please. I am having trouble with what should be the easy bit, the audio amp/ low pass filter. With the component values shown I am not getting the signal levels quoted in the text. DC voltages are close to spec. The digital bit works fine, so far. Whilst I check my wiring (again!) I would appreciate some reassurance from any successful constructors.
Thanks.
Tom

Hello Tom,
I have built that unit (etched my own pcb) and it seems to work okay on the bench. I am NOT impressed with the performance in the real world though... Introduce some noise on the signal and the filter doesn't seem to work quite right. I know this doesn't answer your question, but it is all I know about it from personal experence. I do know someone else who built and currently uses his. It seems to work okay for him, although I have not looked at it with any test equipment... for all I know it could be doing the same thing mine is. Good luck!

Re:

4-1000 Schematics: You can contact the Eimac Distributor in your country
and ask for a Amateur Application notes index. Within that index, there are
several App Notes that pertain to the 4-1000A tube. Complete schematics
and details on how to build that amp, and also dozens of other, related
hands on topics on amp building, in general. My recollection of the
4-1000A in Grounded grid, is that it will put out GOBS of power, uses
quite high Plate voltages, and requires lots of drive, maybe 150 watts
drive at HF. I run a pair of 4-400A's on CW which put out about 800 to
1000 watts (output) when driven with 100 watt exciter. This is with
about 2700 volts on the plate, under load, and 550 ma plate current. I
would like to add a third tube, sometime, as they are cheap, sometimes free
if you know a friendly Radio Engineer, who is a ham. Three 4-400As
should easily loaf along at a full 1500 watts output. Make sure you also get
the App Notes that apply to cooling requirements to these tubes. The
4-1000A tube has a ceramic surround at the base, with metal ring that
adds a fair amount of backpressure when combined with the glass chimney.
Use a squirrel cage fan (NOT A "MUFFIN" FAN) for cooling.
In the U.S. Eimac has 2 toll free numbers that info can be obtained from:
San Carlos (CA) office: (800) 423-4622, Utah: (800) 453-9428.
BTW, I have no connection, or commercial interests in Eimac.
73, and QRO to you.... Best DX, de Pat, AA6EG, aa6eg@tmx.com

Hi Bill, your right these things do turn unto flames...Bill I think you mis read what I said. I am an extra Class and have been so for 10 years running. What I was saying is , it seems like it is the no code hams who want to do away with the code all together. I feel they would like to remove the code portion of the bands all together to add more voice FREQs. I don't think, there are that many people who learn the code to 13 wpm and upgraded to general who really want to do away with all code. I truly believe if they did away with the code completely, the code portion of the bands would also go too. Hey I like CODE ! And I really think more people would too if they truly gave it a try. Not too many kids like learning another Lang in high school either, but if they do truly learn one, then it is of great help and you know it really isn't all that bad once it is learn.

By the way Bill ref to the other aspects of ham radio.
I built my repeater on 2 meters, I'm linked with 3 other sites, I built my own voter board, a few QRP low band gear, a kilo watt amp home brew using 813's, a 2 meter transmitter 1&1/2" x 1&1/2"using a 9 volt battery,
I'm now playing with an IR transmitter. All this because I became a ham and wanted to explore all I could. I'm not an electronics wizard but I know how to read , research, and apply. By the Way I'm also a V.E. and have lic. Many no code hams, but did you know the ARRL as stated that 90% of the no code ticket holders have never upgraded, that means they never even tried to learn the 5 W.P.M. code. Now Bill, is 5 wpm really that hard to learn ? Or is it a lack of trying ? That would give them 10 meter privileges and 10 meters is a great band when it's open. I'll admit though, the 6 meter band is a lot busier now because no code is required. I feel they are really missing out on a lot, you know ,low band gear is a lot easier to build than VHF gear, and a lot of fun to use too.

Exactly! What about hospitals (where one goes to get healed supposedly) and their 5 kilowatt ERP pager antennas? I'm serious, I've seen the specs required by some hospitals here in Md for their paging network. Not to mention commercial pagers.

Like the new bogus stricter vehicle emmissions laws, if you don't meet EPA requirement you have to pay waiver penalty (in Maryland, $150 for 2 years).

Sounds like another money-grubbing scam from Washington.

In this thread there has been mentioned of the FCC study on this issue. A number of months ago I downloaded this " article " for work it prints out to be over 70 pages. We have nbeen looking at this issue for a while now casually. It was worth the time to download , lots of information was surprized to see how many typre of antennas the FCC used for testing and the tables and charts with test results included..
Download and print it today. Take a few nights to read and digest it.

Robert,

It may sound fun (when I was in college, we tried to do the same thing, but were unsuccessful, luckily.) If you do succeed, you WILL most likely be caught, unless you are in an area with almost no radio stations. As an assistant engineer at an FM station with several translators, we regularly monitor the band with a spectrum analyzer and would most likely find a 'pirate' station within a few days of it's debut. I'm sure you've read the posts from others outlining the fines.

Radio is an appealing hobby. I'm sure your intent is not to break the law. Why not go about it through the existing channels? If your desire is to communicate, try amateur radio, it's lots of fun! If your goal is to get your music 'on the air', seek out a local college or technical school radio station. I'm involved in both amateur radio and broadcast radio, a rewarding hobby and career. Good luck!

Cooledit allows you to highlight any given part of a wav file and
do a fft on it. It has another mode where you can either move the
cursor along and fft a given point or highlight a given area and
"scan" it and get an averaged fft.
Syntrillium(spelling?) has a web site and Cooledit is also at many of
the ftp archives. You can use any two of its many features as an
unregistered user. For $50(us) you can register it and use all of the
effects at once. Nice program but I use WAVE by Turtle Beach. Wave
gives you a 3D plot of signal/frequency/time as a "topographic" map
type display. There is a freeware program that allows FFT called
(I think)Spectogram. It is up to version 2.3 and will play, record and
fft a wav file.
If you ned real time FFT, there are some programs that use a Sound
Blaster. FFT4 comes to mind. I grabbed it at the OAK.OAKLAND ftp site,
but that site might be gone now.
If you can not find FFT4 or Spectrum let me know and I will try and look
thru my notes and find where I got them.
Good luck.

You'll get a T1 connection which you could attach to your router.

I hope you don't consider the school application too critical.
Remember, part 15 devices must put up with any interference they
receive. Not only that, if you happen to interfere with anyone
else, you can be requested to shut down.

I have looked at the early lynx receivers. What they do is add
their own PN code at about eight times the data rate. That in
itself wouldn't be a big deal, except that the receive side is
wide open. They use a very wideband discriminator to receive
the whole FSK PN+signal mess. Then they digitally xor
themselves with the incoming PN signal. It will work, until
some stronger signal appears anywhere in the passband. Then
the discriminator goes in to capture and you're screwed.

Lynx is relying on the very low activity in the 2 GHz band to get
away with this stupid trick. That situation is likely to change
soon. If you expect PCS to show up anytime soon, you had best
avoid this stuff...

The Lynx, like many other products, uses that military favorite
for stealth and robustness, Spread Spectrum, which was just described
accurately in a technical sense [modulating/multiplying the data
signal with a pn code N-times faster....].

I agree that PCS landing on your receiver will probably mean
kaput, but SS is really intended to overcome the impairments
of single-frequency interferers, and to "despread" any kind of
un-correlated interference.

Rules permit some very small amount of single-frequency power to be
transmitted in these bands, or if spread spectrum, up to [please correct
me] a WATT!, so long as the signal density [megavolts per cubic furlong
or something] is kept low enough - that's done with the pn spreading code.

Now, SOME makers lie thru their teeth about spreading gain. Can't say
for sure about W. Multiplex, but they're a reputable outfit. If the
gain figures hold up [as stated in the FCC rules] then this will be
BETTER than that narrow front end at a milliwatt etc....

flame away....

Here are a few suggestions:

1) A 23 dBm mixer such as Mini-Circuits RAY-3 (23 dBm LO) lists 63 dB for the 2RF-LO spur for an input RF level of 0 dBm. This is pretty good.

2) If you can reduce the gain (or the signal level) ahead of the mixer by X dB, the rejection of this spur will improve by 2X dB.

3) The harmonic intermodulation spurs for mixers are specified for some particular RF signal level such as 0 dBm or -10 dBm etc. 0 dBm is a *very* strong signal.

4) If some particular local station is causing trouble, consider a trap circuit to reject that frequency

The ARRL handbook from a few years back featured a 160M amp based
on the 4-1000A. (I think it was 1991.) It's trivial to scale
the tank circuit for the higher frequencies, based on information
in other projects and handbooks.

As frequently as hams ask for schematics and information contained in
older editions of the ARRL Handbook, you wonder why the ARRL doesn't
publish these on CD-ROM.

League, are you listening?

Hello Rudi,
This can be done with a single transistor, although it would be better to use a pair of them for class ab operation. The only problem with this type of circuit is that the PCB requires special track widths and such to properly match the output impedance of the transistor(s) to the line load. Something MUCH simpler to do is get one of the class ab hybrid amps and go from there. All you will need is a TR switch and power supply. They sell for $50 to $100 depending on frequency, bandwidth, gain, and power handling capacity. I have used these before in ATV equipment, it couldn't be any easier!

Yeh right, what planet are you from ? As somebody who has been through
many zoning restriction tower "battles" this whole EPA bull will be used
as just another tool to prevent us from putting up efficient antennas.
Been there done that. If I didnt have a decent tower now (which probably
is worthless with these new restrictions) I would NEVER go through the
hassles again.

From: tomb@lsid.hp.com
Message-ID: <4ufu80$7hr@hpcvsnz.cv.hp.com>
Source record: 103423

In an earlier followup, I wrote:
: Todd Owen (ke4udn@amsat.org) wrote:
: : How many microseconds does it take for a PIN diode to switch?

: Depends on the diode and the forward and reverse currents. It can
: be well under a microsecond for some diodes. Seems to me there is an
: application note that covers things like this in the HP Microwave
: and RF Designer's Catalog.

I looked up some HP PIN diodes and note that the reverse recovery time is very similar to the minimum carrier lifetime, which shouldn't be any big surprise. In particular I didn't find ANY PIN diodes that we make that list carrier lifetimes as long at a microsecond. They are mostly in the range of 30nS or so to about 400nS. The reverse recovery test is with 20mA forward current, and 10 volts reverse, with recovery to "90%" (of what?? It appears from the test circuit to be to 10% of the initial forward current. And the 10 volts reverse is through 100 ohms of external resistance, so it's maximum 100mA.) With fast-switching PIN diodes, switching times in the 10nS region are possible, but of course it wouldn't make much sense to use a diode with such low carrier lifetime to switch a 30MHz signal... gotta use a diode appropriate to the application.

This will add amplitude noise sidebands and add heating losses in the diodes.
Better is to suppress only the even harmonics, and drive the diode ring with
a saturated square wave. This is, of course, a matter of opinion, as there
are arguments for both ways.

250. Ring diode mixes and spurious signals

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-09 00:00:00 UTC
From: larsm@lin.foa.se
Message-ID: <4uenl1$ng9@mercur.foa.se>
Source record: 103426

Hi
while starting a design for a fairly wide-band converter using a ring-diode mixer, all the usual unwanted signals appeared. One signal that is really a pain-in-the-a** is 2*RF-LO. Data sheets shows supression of 55-60 dB w r t input signal. Filtering will not help as this spur is generated within the mixer. Changing IF is no option as this is fixed.

Well while discussing this problem with a friend, he thold me he have had similar problems while designing a s/w receiver.
Example: assume RF 5 MHz and a IF of 40 MF. This leads to a LO of 45 MHz. Apply a 2.5 MHz unwanted signal and presto this shows up only 60 dB down.

OK, in this example the use of a sub-octave pre-selector would solve the problem, but there seems to be other solutions....

Doing this test with a Watkins Johnsson WJ-8711 with only a lp-filter ahead of the first mixer shows excellent rejection.
Is there a smart way of getting this "second -order" spurs to be supressed 90-100 dB? Is it possible to acheive this kind of balance over any temperature range and component drift?

Suggestions and/or comments are really wellcome!

From: Mitch Kobierowski <mskobier@3-cities.com>
Message-ID: <320BF3EA.4211@3-cities.com>
Source record: 103427

Hello all,
I am trying to find some specific information about the filament choke that I am installing in my home brew (4) 811A amplifer. I inhertied the partially completed unit a couple of years ago. I repaired, re-designed, and put on the air this amp. It worked great. I have recently decided to ad the WARC bands and 160M to the amp. I discovered that the filament choke didn't have enough reactance for 160M. The choke measured approx. 20 micro/h. I have looked back through all of my available reference material and haven't found any info on the mod I am doing. I purchased a 7.5 inch /.5 inch diameter #61 ferite rod. the number of turns that are required seem to be between 25 and 35 bifilar wound turns. I haven't been able to find a specific design that has been proven to be adequate. If anyone has any information on this particular subject, I would really apreciate it. you can e-mail me at mskobier@3-cities.com or post back to this newsgroup. thanks in advance.

The problem is that the FCC and big business have a virtual lock on all
RF spectrum. For example - to setup a small radio station is beyond the
fiscal abilities of most people and communities because the big guys
suck up spectrum. The perfect example of that is WDGE here in Providence
that broadcasts on both 99.7 and 100.3 which is a complete waste of
spectrum.

BTW - Christian Radio? Like there aren't enough churches and bible thumpers
around?

Tony (Who remembers that Christians are responsible for the best and
bloodiest of wars.)

>MHz. Apply a 2.5 MHz unwanted signal and presto this shows up only 60
>dB down.

First a correction. The example you give is not 2*RF-LO but
rather LO-2*RF.

Second, have you measured the rate of change of the spurious IF
signal with respect to the rate of change of the 2.5 MHz
interfering signal? If it is LO-2*RF, the ratio should be -2.
But what if it was actually the 16th harmonic of the 2.5 MHz.
input blowing into the IF? Then it would have a ratio
of +16.

If it was an IF harmonic, then you may be able to filter out only
the high order harmonics of 2.5 MHz. and let 5 MHz. go through.

Third, did you carefully filter the 2.5 MHz. unwanted signal to
guarantee that the 2.5 MHz. source did not have harmonics at
5 MHz.? You probably did, but just wanted to make sure.

Fourth, it is extremely important to filter out of the LO drive
signal all harmonics, especially the even ones and in particular the
2nd harmonic. Failure to do so will seriously degrade IM performance.

Fifth, regarding your sub-harmonic filter: if you have any
RF amplifiers in front of the mixer, you'll have to put the
filter between the amplifier and the mixer, unless the amplifier
distortion is negligible.

>Doing this test with a Watkins Johnsson WJ-8711 with only a lp-filter

I have been experimenting with the WJ M9E, which is the best
HF mixer (with DC coupled IF, at least) that I have found.

The diodes should all drift together, so temperature shouldn't
be super important for distortion, although it can affect
isolation.

>>|Look/listen around.

>>|Andy

I think the idea in so far as enforceability is concerned is so the powers-that-be can have one more thing to hang over your head just in case you do something to displease them.

I am not completely prepared to debate this, nor do I think this is the proper forum(s) to do so in, but I have come to the conclusion that the government has decided that the normal legal / legislative process has become ineffective in dealing with the issues (read: percieved *threats*)

Our politicians spend so much time preening and posturing before the American people, rather than dealing with substantiative issues, that the entire political process has become more of a circus side show, than an exercise in effective government. I am not altogether convinced that the people we elect to office are even qualified to understand the issues, much less deal with them.

So they sidestep the whole issue by creating a multitude of agencies with administrative (read dictatorial) authority over just about every aspect of our lives. These agencies rule by fiat, and in many cases are not accountable to anybody. (Canonical example: The I.R.S.) There are so many rules and regulations, so haphazardly written, and in some cases, mutually contradictory, that I suspect that no matter what you do, you are going to be in violation or one or more. Period. This sets the stage for selective enforcement, which means that if you attract thier (agency) attention, you get stomped on.

This flap over environmental impact statements is just another example of a government spinning wildly out of control.

Unfortunately, I am not a politician, just a humble electronics enthusiast, so what can I do?

262. 3-Phase AC question

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-10 00:00:00 UTC
From: ccsys@interport.net
Message-ID: <320c05bf.6850931@news.interport.net>
Source record: 103292

I have a Lambda switch-mode power supply with a 3-phase input requirement. Being a switch-mode supply would this work acceptably using both sides (and the neutral) of the 220 line (and leaving one input disconnected?)

From a brief examination the three inputs appear to be in the standard 4-diode "full-wave" rectifier configuration. The outputs of the bridges appear to be connected together and to filter caps. I assume that the ripple will be increased which may require greater capacitance.

Any ideas or suggestions?

Common PIN diodes have carrier lifetimes between 1 and 40 microseconds, but these are by no means the technical limits.

As a general rule..the larger the junction, the slower the diode. Slow diodes are necessary on low frequencies. Long carrier lifetimes prevent the diode from acting like a conventional rectifier.

Use a diode with a carrier lifetime of five to ten times the period of the operating frequency. That requires a 2.5 - 5 uS diode for 1.8 MHz.

>>|Good Luck

>>|Steve Muther WF6R

Several ideas come to mind.

First, if you look around, it might be possible to find several
different kinds of these ultrasonic emitter/detectors. Determine
their frequency responses, and pick a set whose combined requency
response spans the range of interest.

I don't think you can effectively parallel these transducers, so I'd
suggest building a simple emitter follower preamp for each sensor, and
combine the outputs. A pot in the output of each preamp would allow
you to compensate for varying sensitivities of each sensor.

Another possibility would to be get an extended range piezo tweeter
and try to use it as a microphone. However, I believe these cut off
around 50 KHz or so.

I have no idea how much a commercial microphone for this range would cost, or even if they are available.

Just some ideas....

I have a limited number of EF Johnson Fleetcom II UHF rigs for sale.

These are easily converted to repeaters. I can provide the unit 2 ways.

As-Is - $50.00 + $10.00 s&h You do all of the conversion, alignment, recrystaling, etc. I will provide instructions for the conversion & a copy of service manual.

Ready-To-Go Repeater $300.00 + $10.00 s&h Fleetcom II converted to repeater use, crystaled to your freqs, tuned and aligned, simple controler w/id. You still need to provide a duplexer, and antenna. w/manual

These units are all pulled from service and tested & aligned on 468mhz.

I also have a limited number of service manuals for older commercial equipment. E-Mial your needs and I'll see what I can do.

Other Services available: (All prices + s&h)

Reprogramming of commercial equipment to Amatuer freqs - $35.00
Equipment Repair - $60.00/hr + parts (1/2 hr min, estimate if repair will take more than 2 hr.)
Custom Cables
'Most anything else your rig might need.

E-mail your needs to:
kproctor@ix.netcom.com

> >Is there lead in the smoke?
>

Yes - there are some problems if you get it full into the lung. Alan's advice is good, and if you use a small fan the danger from tox is low. Handling lead will in time cause a cumulative buildup in you, again at a low level. DON'T put it in your mouth!! - ever. The most common problem is a strange tightness in the top of the chest, and a shortness of breath that is very like asthma, but happens to everyone. It can also trigger true asthmatics into fairly severe attacks. The symptom goes away after a couple of hours in the fresh air.

Beware the toxic products if you are tinning coil wire. If you can smell it strong enough to identify it as decomposing varnish, you are several times over the top.

Hope this helps..

This is reallly the experiment to comment on. This receiver using a
quad FET switching mixer SD5400 (or something, equvialent to the
SI8900 stuff, never seem to remember the exact part numbers). Anyway
our W/J rx shows very good rejection of half-frequecy of the wanted
signal.
How come???

>I have been experimenting with the WJ M9E, which is the best
>HF mixer (with DC coupled IF, at least) that I have found.
>The diodes should all drift together, so temperature shouldn't
>be super important for distortion, although it can affect

Hmmm, numbers shows a clear improvement on the Mini-Circuits
high-levle mixers 2RF-LO 83 dB down compared to TFM2H (data on the
TFM3H shows 77 dB, this I have to confirm). But then the price and
availability is a 10 dB advantage for Mini Circuits

What I'm actually wants to do is to down-convert a wide-band IF to a
lower freq and then A/D-convert it. The A/D needs +4 dBm FS and the
max sig power at the high IF is -18 dBm. I must have at least 65-70 dB
of spur-free dynamic range! Usually one can lessen the problem
associated with harmonics by changing IF's an LO but not here.
If the mixing is sorted out with enough DR, the next thing is
harmonics in the low IF. With this wide-band low freq IF, the lowest
IF will generate a secon harmonic within the pass-band. I will
probably be forced to use a balanced amplifier to get enough
supression.

IF is 40 +/-5 MHz and down-converted to 12.8+/- 5 MHz, LO is fixed
52.8 MHz.

Well, I am going to starting a college project soon, for my
Electonics Technologist Course. What I am proposing to build is a VHF
repeater. To start off with just a very basic system. Then as time
permits, to continue to enhance it, with higher power, phone patch, and
voice messaging.
What I am looking for, is any information on building a system,
Transiever, and power supply, maybe a kit, or documentation. Anything
that might help me get the basic system done quickly, to try and dedicate
more time to the features.
I have just started to preform my research, so any information
that you have would be appreciated, anything at all. I have 6 months to
complete this project, PCB'ed, documented, and functioning within this
time limit, so time is of the essence.
Thanks in advance to all!
Mike Russell

Thanks for the info, Tom. Can you give us a specific example of
a 40 microsecond diode? We didn't know they were available.
Does Microsemi make them? I thought the technical limit on
the carrier lifetime had to do with how pure they can make the
silicon in the "intrinsic" region. Anyway, a 40 microsecond
diode would be quite interesting to experiment with.

Hello out there .....

Before I set about re-inventing the wheel ..

Has anyone already succesfully converteda Cobra 138-XLR (A) (the PLL version - NOT the early rock bound block) to the UPPER part of 10 Metres ?

I did shift one up to the bottom end of the band - but here in Australia that is no quite high enough for my class of licence.

Once converted I will FM it and add some digital stuff for repeater offset control etc - THAT part is easy !

O.k off you go - look in your "Mods" file for me - Please !!

Thank for reading this, hear from you soon ?

Glen

VK5ZCF (+ A number of other licences on LOTSA frequencies)

>the discriminator goes in to capture and you're screwed.

Most of the existing 900 MHz DS SS systems in use today use 10-12 bit spreading sequences which are symbol-synchronous. These codes are barely capable of providing the FCC-required 10 dB processing gain (under ideal circumstances).

Most are despreading at baseband (broadband all the way down) so they are subject to interference ... some are, as you relate, actually wideband digital FM with limiter-discriminator type receivers, others are BPSK/QPSK with linear receive chains and AGC ... however they are still subject to strong interferors.

From: af389@lafn.ORG
Message-ID: <320D4686.704B@lafn.org>
Source record: 103313

Hi,

Sound Blaster cards are used in many different Ham Radio applications.
My question concerns if clones of Sound Blaster 16 bit cards can be used
or must real Sound Blaster cards be used for these Ham Applications?

Is there something unique about the real 16 bit Sound Blaster cards that
would prevent software like you are discussing from working with clone
cards of the 16bit Sound Blaster?

In a system I am buying they propose to install a sound card, called an
"OPTI" card rather than a true 16 bit Sound Blaster card. I am not sure
if this is a clone of the SB 16, but they say the OPTI is superior to the
real SB 16 card.

Thanks for any thoughts.

284. Pi- and T-filters

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-11 00:00:00 UTC
From: Peter_Janssen <pjanssen@cuci.nl>
Message-ID: <320DE630.646F@cuci.nl>
Source record: 103314

I want to construct some High-Pass and Band-Pass filters for HF/VHF-freq.
For the caLculations I use the shareware-program FILTRY20.
In the program I can choose between a Pi- and a T-filter configuration. Both give the same function (for example High-Pass), freq., impedance, etc.
Generally T-filters are easier to build: less L's, more C's. Can I choose between Pi- and T-configurations on this practical ground or is there a difference in performance between Pi- and T-filters which is not mentioned by the program?

Source record: 103318

Hello All Concerned:

I worked as a bench technican for about a year straight. I was a technican Friday, I would catch all types of repair and assembly work, which meant the I was soldering all day long. At first the smoke from the soldering iron did not bother me, but after afew days, I could tell that I shouldn't being breathing the fumes and smoke from the soldering iron.

So I asked my supervisor for a small equipement fan to blow the fumes and smoke away from my face. I finnialy ended up with two fans, one to blow the smoke away from my face, and the other fan mounted up one the top of the work bench, blowing upwards. This worked great, even when I used a high wattage soldering iron, 100 & 250 watt irons.

This kept me from feeling better, and as if I smoked two packs of Camels a day.

Jay.

290. Need help Identifying Micor .mobile?. repeater

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-11 00:00:00 UTC
From: sidener@saucer.cc.umr.edu
Message-ID: <4ulm0b$2m7@hptemp1.cc.umr.edu>
Source record: 103320

Hi, I just got hold of a Motorola Micor which I need help identifying.

It's model number is: Q2033A SN# 539CNW0006

It is a UHF (462 MHz) radio with 10 reciever channel elements.
There isn't any place for TX elements so I assume it derrives the TX freq
from the RX channel elements.

On the end of the radio there is n extension aout 5 inches long. In that
extension there is a duplexer! It is set up on a 5MHz split.

The radio has two RF connectors on top 1 UHF and 1 BNC.

The radio also has a tone board.

This looks like a perfect candidate for making a 440MHz repeater.

Can anyone give me more info on this radio? I have a VHF Micor mobile
manual and a 50MHz Micor repeater manual, but nothing I have comes close
to this. I need to find someone with a manual.

Also, why does it have two RF connectors at the top and can I use a
regular Micor control head with it?

Any help would be appreciated.

Thanks,

Scott Sidener

The Ham Radio Online web is still "on the air." However, our new web server located in California's Silicon Valley lost power during the massive west coast power outage this weekend and as of Sunday morning (U.S.) 11 August the http web server is still not functioning. Our ftp access to the web site came back up this morning so we've updated the files. We assume the web server will be brought back online by Monday.

You can access the Ham Radio Online web site at:
http://206.13.40.11/
(www.hamradio-online.com when InterNIC gets their directory updated.) You can also check for updates at our backup web address:
http://www.accessone.com/~vbook/hronline.htm

We've completely redesigned the "List of Other Ham Radio web sites", "Commercial Products Directory" and the Ham Radio Online Library for easier access to all the information that is stored online. It really looks cool and we had a lot of fun learning how to use "frames" for the web pages.

Thanks!

actually, wouldn't a TV antenna work for 6 and 220 without too much effort?
and 2m might just work on an LP type antenna...will have to see if it's possible
to do some measurements....wouldn't expect there to be too much modification
needed for the use of an existing TV antenna as a transmitting antenna in
the amateur service -- short of adding a balun (6:1 for 300:50 transformation) and
maybe doing some minor changes to the element lengths.

303. TCM2912DJ PCM Line Filter ICs-Info needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-12 00:00:00 UTC
From: jah@ois.com.au
Message-ID: <4um56e$8au@news.mel.aone.net.au>
Source record: 103333

I picked up some TCM2912DJ PCM Line Filter ICs by Texas Instruments
but can't find any info. on them in TI catalogues or on the TI www
database. These are 16 pin DIL chips made in Japan. Can anyone help
with specs and pinouts. Many thanks.

: Can anyone tell me the operating frequencies and power levels of speed
: type radar systems used by Law Enforcement?

: Thanks, Tom

X-band: 10.500 to 10.550 GHz
K-band: 24.050 to 24.250 GHz, considered to be more accurate than X-band.
Ka-band: 34.200 to 35.200 GHz, as originally authorized by FCC in 1982.
Ka-band: 33.400 to 36.000, after the 1992 expansion. This is the wide Ka.

The X-band has a greater range than the others, but all are in the low
milliwatt range.

Lidar: 904 nanometer wavelength.

To "Rigless" from Kerry in Texas,

Man, I feel like I'm answering a personal ad or something! My wife
has been pretty much dulled by the catalogs. She got her ticket and
now she gets the catalogs!

More to the point, I just built a NorCal 40A, from Wilderness Radio.
I think the kit is $135 or so, do a web search for NorCal or
Wilderness Radio. It is a qrp transceiver, about 2-3 watts, covers a
40-50 KHz segment of 40 meters, has a superhet rx and a great 400 Hz
4-pole xtal filter.

I've had mine for about 2 months now and am having a ball with it. It
took me about 5 hrs to build, although some people take 15 hrs. It
has excellent instructions, similar to Heathkit. If you are handy
with a soldering iron, you won't have any problems. Sorry, I read the
engineer part, but some of my EE friends don't know which end of the
iron to hold until it has been plugged in for a while!

73 es good luck with the project and the wife!

306. Re: 4-1000A Amp Schematics Wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-12 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <4umklb$75u@newsbf02.news.aol.com>
Source record: 103336

Hi All,

Whatever book thiss data is from, it is not correct:

>Class B SSB GG (g1 and g2 grounded)
>Va= 4 kV
>Ia= 120 to 670 mA, Ig2= 0 to 80 mA, Ig1= 0 to 150 mA
>Wdrive= 105 W, Wout= 1870 W

The 4-1000 would be in AB2, not B. Conduction angle would be more than 180 degrees and less than 360 (AB), the 2 would indicate grid current.

At 4000 volts of full load anode voltage, expect to make 1500 watts output with 115-130 watts of drive. The exact value will vary with circuit influences and the cathode driving impedance of the particular 4-1000A you have.

The 4-1000A also suffers from stability problems at high anode voltages. Long grid leads are the primary cause of instability. Sometimes builders get lucky, but many times a 4-1000A gives the builder "fits".

A 4-1000A's greatest tendency to oscillate is, depending on the circuit layout, between 50 and 100 MHz. Since the self-oscillation frequency is relatively close to ten meters, conventional single reactance parasitic suppressors often cause problems above fifteen meters. The best way to stabilize the 4-1000A is with a RLC or RLCL type suppression circuit resonant at the low end of the FM broadcast band.

IMD performance will not be nearly as good as most tubes designed with SSB in mind, but should be acceptable in most Amateur service if the amplifier is loaded heavily enough.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
August 18th, 1996
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

The PI network can "absorb" stray capacitances to ground that are present
in the output of the driving circuit and the input of the following
circuit. The TEE network does not do this.

MBTA radios in Boston (a trunked system, I think) use MCW to ID regularly. Sit near the front of almost any subway car, bus, or train and it can be clearly heard. Sounds like it is about 25 wpm.

Anyone know of any commercial uses of CW other than automated IDs?

>We didn't know they were available.
>Does Microsemi make them?

The longest carrier lifetime Microsemi diode has a typical lifetime of 25 uS, such as a 2001 diode. We used to order 40 uS diodes from a defunct manufacturer on the east coast, I'm sure someone else could or does make one. We used it in a VLF medical application. Maybe they went out of business because the parts weren't really what they said, like those Russian 3-500's that are really made in China, hi.

>I thought the technical limit on
>the carrier lifetime had to do with how pure they can make the
>silicon in the "intrinsic" region. Anyway, a 40 microsecond
>diode would be quite interesting to experiment with.

The manufacturers told me it also has a lot to do with junction size, so be prepared to spend some money...we paid ~ $25 a diode. As I recall, the chip size was around 200 mils. The capacitance was rather high at low frequencies.

Unless you're doing low VLF work, the 2000 series would be a $10 solution that would get you in the 25 uS carrier lifetime range with an off the shelf part.

On second thought this may not be true. The TEE network can make the
stray C part of the TEE network. For example, if we start with a PI
network, decrease the C values to "absorb" the stray C, then we do a PI
to TEE transformation of the *remaining* PI network, everything works OK
if the TEE components L and C are positive values.

>>>Wdrive= 105 W, Wout= 1870 W

Hi Claude,

They could have been more careful in that ad, hi.

But the error is understandable since the 4-1000A was never designed to be used in grounded grid service. I doubt the ad source was the Varian engineering department, and I think I might know the source of the ad data.

The fact remains class B is a conduction angle of exactly 180 degrees (zero plate current under no signal operating conditions). If the tube has any zero signal plate current, it is class AB. Class B amplifiers do not offer noticably better efficiency over class AB, but they do have noticably poorer IMD performance and somewhat lower gain.

Eimac data sheets, and I believe I have all the sheets published, do not list grounded grid operation of the 4-1000A. It certainly can be done (I've done it several times myself) but it isn't the best tube for GG service. The 3-1000Z and 3CX1200A and D7 triodes are of the same general family but have more gain and better IMD performance.

Because the internal strucing is very similar, all of these tubes offer stability problems to the builder. They all share low self-neutralizing frequencies, caused by the long grid structure and internal grid leads.

The 4-1000A has the lowest GG power gain of all these tubes, because the driving impedance is so high. A typical 3CX1200, with higher gain (lower driving impedance), will barely make 1500 watts with 100 watts of drive at 3600 volts. A 4-1000 will do much worse.

I'm not trying to discourage a builder, just make him aware that gain is limited without high anode voltages....and if high anode voltages are used, stability almost always becomes a difficult issue. A GG 4-1000A would not make the top ten list of lowest IMD performance tubes either,

but they are pretty to look at and inexpensive (when used) to buy.

Yes, the famous "low dipoles" work great for NVIS propagation. In
the military, this is done frequently with whips tied over into a
semicircle. For good, short- to medium-range communications with
no skip zone, they can't be beat, as long as the guy you're trying
to talk to doesn't have a vertical! ;-)

The specifics of the WRSAME or SAME protocol have not been made
public, and probably never will be, at least not if the NWS has
anything to say about it - they don't want hackers broadcasting
bogus severe weather warnings!

: the program?

Such filters assume particular source and load impedances. It may be that
your source and/or load are not the design impedance, and one or the other
of the two configurations may be more tolerant of that that the other.

In addition, the impedance presented by the filter to out-of-band energry
is very different in the two cases: the pi highpass will look like a very
low impedance at low frequencies, but the T highpass will look like a very
high impedance at low frequencies. That may or may not be important to
you.

Thanks for your response, Randy.

I have not had chance to do much since I posted my question, but I suspect R9 in the circuit diagram should perhaps be 22k, not 22 ohms. 22 ohms would only give a gain of about one in the passband.

I have a Dopler DF circuit that originated in "73" Magazine in the mid 80's that I might try instead, if all else fails. It is very similar to the Roanoke circuit but uses 300Hz instead of 500Hz. Also it used an RF summer instead of hard diode switching of the antennas - unfortunately there was no listing of the PROM used to give the correct bias to the FETs. I don't suppose it would be available now, so I might end up with a mixture of the two circuits.

Cheers.

Tom.

327. Re:Repeater College Project

Newsgroup: rec.radio.amateur.homebrew

Mike Russel asked about a "simple" VHF repeater.
Mike:
The hardest part of a repeater is going to be getting an official repeater pair on any frequency below 450MHz. Most places those frequencies are full. You might look at doing a 6 meter repeater, since most places probably don't already have more than 1 or 2 repeaters on that band.

The simplest way to do a repeater is to buy an inexpensive separate tx board and rx board. Probably the hardest RF part of a repeater system design is getting the transmitter not to clobber the receiver. I would suggest that you look at ways to keep the 2 antennas separated both vertically and horizontally. Since this is *primarily* a learning experience and I suspect that cost is as much a problem as anything, you want to stay away from things like cavities and other things necessary when using one antenna. That way you can concentrate your design efforts on the controller. The *magic* of repeaters is in the controller and the duplexor (that I just suggested you not use).

If you have specific questions as your project proceeds, there will be plenty here with opinions for you.

There are quite a few still active around 4, 6, 8, 12, 16 MHz. Several
can be heard even sending CW traffic around 8600 kHz each evening.

I buit one some years ago to detect sparks from Hydro poles
using a salvaged piezo cell from an old Jerrold cable converter.
You can also use a Piezo tweeter RS 40-1382.

There was an interesting circuit in the 1990 "Electronic
Hobbyist handbook" (Pop. Elect) using a 4066 quad bilateral
switch as a balanced mixer, 2 2N3904, 1 TL082, 1 LM386.
I think there was a mistake in one of the pinout in the
schematic the magazine gave.

Sounds like a nifty piece of legislation we have up here now called
EMCAB-2. Part of the reality of it is the necessary tests involve taking
measurments every metre in a cubed grid about the station! Wonder how
much that one is going to cost. It's been stressed at a few meetings that
it's not likely to get to that stage and might only be applied in the
event of an otherwise unresolvable EMI problem, not exactly with you have
to put up with. 73 John VE6OTC

I have a 2 metre handy that on low power produces 0.5 of a watt and on high power 3 or 5 watts depending on whether it is run with batteries or from a power supply.

I also have a linear amplifier for 2 metres use that produces 80 watts or more with 2 watts of drive which is too much for me. You are supposed to be able to drive the amp with a min of 0.5 watt and get 30 out but mine will not work properly at that power and the automatic switching flutters in and out.

I want to drive it with 1 watt but my rig does not produce that .
To cut a long story short is it possible to attenuate the signal between the transceiver and amp down 1 watt .

Any suggestions/comments will be gratefully received.

>an easy build and good>working inductance meter !?>

If you only need to measure in the microhenry range, see

"The Handy Inductance Bridge" by KB4ZGC, in 73 Amateur Radio, May '91.

Remembered two more inductance articles (and which may be easier to build than the one above);

"Easy to Build Inductance Meter" by Ed Marriner W6XM in Ham Radio (USA); Apr '82. Uses discrete components, with no fancy parts,

and

"Simple Inductance Meter" by Frank Brumbaugh KB4ZGC in 73 Amateur Radio; June '96. Again, no fancy parts.

73, Drew, VK3XU.

Hello,

I have a HILLS RF Video Exciter unit. apparently these units where used as distrubution units in hotels/motels
etc. It is up and running on 444.250 MHz, one of our VK ATV frequencies. However the output is only around
10mW.

What I would like to get is a CCT (pcb artwork etc) for a little CLASS AB 10mW to 250mW amplifier that I could
build and then fire that output into my existing ATV AMP (M57716 brick).

If you can assist me with anything please drop me a email either personally at my reply address of via the
newsgroups I have posted this to.

Thankyou

Mark

>but they are pretty to look at and inexpensive (when used) to buy.

I agree, Tom. If I'm informed well, the 4-1000A was largely used in many
broadcast transmitters, many of which are still in use today. Considering
that the PA tubes are usually replaced after a given number of hours of
service, there are many such used tubes in the world which are often
available for few money. There is probably where the idea starts to
use them in an amateur radio transmitter. You can have some ones in
stock in order to replace the defective ones when necessary. The service
duty of the amateur radio service is not as severe as the broadcasting
service. I ignore if there is now another better tube which has become
a standard and which will become commonly available as used tube after
a given number of hours of commercial service.

Do you have such an information, Tom ?

RE : Precision Ovened Crystal Oscillators.

I have a number of unused OCXOs 16.384 MHz.
Dimensions 75X50X30mm
These divide by 2 to the power 14 to give 1 kHz to function as the
reference for frequency synthesisers as used in instruments, radio,
cellular, TV Transmitters..
Oscillators are stable to 1 part in ten to the nine i.e. 0.001ppm.
Excellent spectral purity, measurement repeats to 0.0001ppm per second.
Will operate over -40+70C
12 V supply 500mA on warm up
150mA when running@23C
Built in 8V reference so that fine frequency adjustment can be carried
out with external potentiometer.
These units are latest technology incorporating SC cut low ageing
crystals < 1 part in 1 million / year.
Manufacturers one off price approx $500.
Supplied tested with connection diagram.

1 off price from FP Ltd. $75
discount for quantity.

Email for further details.

Rick,

I suggest trying the SW-1 (sold by its designer, Dave Benson NN1G) for about $55 postpaid (he's good in the callbook, write him directly), or the earlier NN1G Mark II transceiver (sold by Dan's Small Parts & Kits, 1-406-258-2782) for $59.95 plus postage.

Both of these are superhet receivers with crystal i-f filters, full QSK, VFO on tx/rx, about 1.5 Watts output, easy to build, and perform well. I have one of each and I like them very much (SW-1 on 40m, NN1G on 20m).

Give 'em a try!

Hi Andrew

I doubt you could get the rated power performance from the supply. The input would certainly suffer from a greater p-p ripple. It would be like loosing power for 1/3 of the time going into the input capacitors, relative to the design ripple parameters. It might work satisfactorily at a de-rated load though.

>Do you have such an information, Tom ?

Unfortunately no, there are some tubes available as medical pull outs that are better to use but have shorter life....the 8877 comes to mind.

It is almost unconditionally stable, and has very high gain and good IMD performance....but has been subject to internal structure failures over the years.

The 3CPX5000 and 3CX3000A and F7 are good and very reliable SSB tubes, but a bit big for most Hams.

The catch 22 is this....

A tube with larger elements (ie 4-1000A, 3-500, 3CX1200A or D7, 811A, 572, 833) is easier to build. The internal dimensions are large and the tube is less subject to internal shorts. The thoriated tungsten filaments these tubes often use offer very long life, and are not subject to permanent stripping from overcurrent or low temperature operation. The emission life is a function of filament hours, more than mild abuse. They make good Ham tubes EXCEPT they are less stable, harder to drive, and have poorer IMD performance.

A tube with small elements (ie 8877, 4CX1000, 3CX800, etc) is harder to build. It has close element spacing with very small elements. They are more subject to overload damage (less thermal mass and closer spaced elements) but have higher gain and better IMD performance. They are more stable, and operate better at higher frequencies. But they also, with indirectly heated oxide cathodes, can be ruined by low filament voltage or excessive emission.

IMHO, the best amateur SSB tube is the 3CX1200Z7 or 3CX3000A or F7. They combine the best of all worlds, long life, stable, and good to excellent IMD performance. The best pull out tube is probably the 8877 for performance, and 4-1000A for cost.

Someday the Russians may make a good triode, that may be a future source.

An easy approach is to use monolithic microwave intergrated circuits...
They are available from MiniCircuits (New York) or from Hewlet Packard /
Avantek. My data is a bit old but for example...
Avantek MSA-0404, ~8 db gain from 100-1000 MHz, +11.5 dbm, 50 ohm out.
Avantek MSA-0520, ~8 db gain from 100-1000 MHz, +23 dbm out.
... Only other parts are a couple of chip in/out blocking capacitors, Vcc
choke (~10 turns, 3-4 mm dia), current limit resistor (depends on part
and supply voltage).

Have Fun! 73,

In respect to the above characteristics, how would the 3-1000Z compare.
This is also a impressive tube to look at and a great room warmer for
those cold shacks.

YES.

Seriously, there IS lead vapor in the smoke, and it IS bad for you. As I recall, lead -collects- in the body, year after year. Lead affects the nervous system, i.e., poisons your brain and makes you stupid, gives you headaches, etc..

Rosin's bad for you too.

At work we use little muffin fans with guards on both sides. We just set 'em on edge on the bench, right behind the board we're working on, and blowing towards the back of the bench. Then the vent fan above the bench picks it up from there. Works great, costs $10.

Um, I may be way off here, but why don't you just put a fuse in the line, and crowbar it? The below may -sound- complicated, but it's really not. A handful of parts, with the advantage of being cheap and off the shelf (read: replaceable).

This is just off the top of my head, but if you're only talking a few KV, you could put a few 1KV SCR's in series, using optocoupler drive on each.

You'll have a series resistor string in parallel with the SCR's for static equalizing anyway, so you can easily derive the trigger circuit power from that.

Sense the current with a series resistor, plus a comparator circuit driving the opto LED's.

You might even get away with using cheap low-current SCR's. They almost always fail 'shorted' (read: melted! the chip, not the package). And who cares if they fail on first use? They're cheap right? I'm assuming here that you're trying to protect against infrequent inadvertent faults.

If you're expecting frequent faults, then of course it'd be worth using SCR's rated for the application (pulse service SCR's). Then you'd just hit reset and replace the fuse. If you have a current-limited supply then you may not even need a fuse. Just crowbar it, and have the detector circuit shut off a primary relay also.

Heck, now that I think about it, why not use a current-limited supply in the first place? If your tube can stand a couple tenths of a second of high current, you could just put a big inductor in series with the plate supply, and use the current detector circuit to shut off the supply. Size the inductor to prevent the current from rising too far within the period it takes to shutoff the supply.

By the way, the old GE SCR Manual, and I think their Opto Handbook, both had circuit examples of how to stack high voltage strings of SCR's.

Good luck with it,

Richard

I have posted this earlier and got some response and sold a few of these kits. I still have about 6 of them for sale.

These kits contain the 128K X 8 Memory upgrade for the KPC-3 along with the DS1215 Clock/Calendar and the 32.768KHz Crystal needed for the clock. I am selling these kits for $15 which includes postage.

I will guarantee the parts to work. If interested please reply via E-Mail.

One problem with switching powel supplies is wideband noise. I used a
stock Yaesu switching PS a while ago, and with low and
shortened antennas the noise was overwhelming. It was OK with high
full-sized antennas.

That PS once gave up at a thunderstorm, something that has never
happend with the conventional PS.

Problem is they are rare and expensive. At the same anode voltage they have more gain than the 4-1000A in GG (due to lower driving impedance). They also have much better GG IMD performance.

They are very unstable compared to tubes like the 8877 or 3CX1200Z7 due to long internal grid leads. This causes the self-neutralizing frequency to be very low and complicates parasitic suppression if ten or 15 meter operation is desired.

All of the problems can be handled, except the expense. Last one I saw at a flea market was in the early 80's.

364. Vacuum tube design question: Cathode followers grid running positive?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-14 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDw551y.E5o@netcom.com>
Source record: 103245

Been playing with vacuum tubes in audio amps, and built a "cathode follower" (kinda like an emitter follower) to provide lower impedance (have plenty of signal voltage, 4V p-p of audio from the CD player's current -to - voltage converter op-amp, the DACs generate current outputs). Tried "self bias" (cathode resistor from neg supply to cathode, grid has large value resistor to neg supply) but the input signal was too big and I got clipping. So, I figured that if I bias the grid to a higher voltage, the cathode would follow (pass enough more current to raise its voltage to make the grid look negative to it again). Got a nice clean undistorted output, but I found the grid was POSITIVE with respect to the cathode by about 1.2 volts, and the grid is drawing about 0.25 ma of current. (measured a DC voltage drop across the grid resistor and ohm's law yields 0.25 ma). The cathode current is about 4.5 ma (again Ohms law deduction).

Am I operating this tube (a 6111 sub-mini triode) in a reasonable environment, or will I burn it up like this? It seems to be acting like a bipolar transistor (positive grid voltage of 1.2 V seems constant, and sucking a little current). I thought tubes want their grids negative compared to the cathode. Tube I'm using (6111) has a gm about 5000, amp factor around 17, medium mu triode, plate current max 8ma, plate resistance something like 3000 ohms (this is from memory, I don't have the manual here at work right now (dont tell the boss!), it's at home).

Multiplying the grid current of 0.00025 A * 1.2 V = 0.0003 watts seems small, is this reasonable calculation, and can the tube take it?

365. Need info on a good tuner design.

Hello all:
I'm trying to figure a good design for a 1000W continuous (AM service) antenna tuner that will have capabilites for balanced, unbalanced, and random wire antennas. Roller inductor tuning is tops but not necessary. Good harmonic suppression is (which rules out the old "pi net" for me). I plan to build the thing in a cabinet that is about half the height of a Collins 75-A2 rcvr. Yes, I'm into the classic stuff so I'll probably finish the tuner in St. James Grey wrinkle also. Any ideas? Cal, N6KYR.

You can try moving the radio away from the monitor and try different orientations of the radio with respect to the monitor to null out the noise. If possible, an outside antenna would be your best bet. You can also try wrapping the power and video cords around some ferrite bars or torroids. Unfortunatly, office machines are not required to meet the the more stringent EMI standards that consumber devices are, consequently, the office is a pretty noisy radio environment.

Good Luck

>BILL WA4LAV was ko4ww

Hi Bill,

Be cautious of the source and how the test was made! At times errorrs creep in (catch that Ian?). The 4-1000A was never speced by Eimac for grounded grid operation.

Eimac measures tubes against one tone of a two tone test, this makes the tube look 6 dB poorer than the PEP method other manufacturers and most Amateurs seem to use.

Also keep in mind the 3-1000Z in not an exceptionally clean GG tube. Compare its data against a 3CX1500.. A 3CX1500 has better than -40 dB IMD performance at the same power level by the same measurement method.

Data taken here on a 4-1000A amplifier I helped a friend build showed the following:

7 MHz with 1500 PEP output at 4700V HV

3rd order -26, fifth order -28

If I used the PEP method the figures would have been -32 and -34 dB, pretty close to the Radio Handbook data. Sometimes data gets a bit jumbled up when it's from multiple sources.

Personally, I consider the 3-1000Z a marginal IMD performance SSB tube for todays congested bands. IMD can sometimes be improved a little by adding a non-bypassed resistor in the RF lead at the tube, but efficiency will also drop and drive power requirements increase.

>Just a thought.

More like a fantasy. I am *very* sorry to read of your loss; statistics show 1 in 4 women will suffer from that form of cancer. But let's please keep emotion out of this ruling. Self-denial that RF cannot cause illness will only hurt yourself, but coming on here and stating that to hundreds of thousands of folks is irresponsible.

Keep your HT at its lowest power setting (not only for health reasons but also to comply with Part 97). Use a speaker mic and hold the HT at arm's length when transmitting (who cares what that will look like - you'll be setting a good example).

Be safe,
Jeff KH2PZ

From: acampane@postbox.acs.ohio-state.edu
Message-ID: <acampane.93.3212CBF4@postbox.acs.ohio-state.edu>
Source record: 103260

Dear HR'rs:

I'm looking for a source of waht we used to call "Microdot" connectors and possibly cable also. It's TINY stuff! I think it's smaller than the SMA variety. I came across MDPT out of the UK, but they are pricey, and I could only view one product (a vacuum feed-through) with my web crawler. So, I'm back into the QSO mode for info.

These connectors have a 10-32 thread, (3/16" O.D.), and the cable is about 0.075" O.D.

I use them on accelerometers. They are issued by B&K and also Wilcoxon.

At the moment, the main thing I need is a 90 degree male connector.

But if anyone knows whatever happened to the Microdot Company, and who took over their product line, I'd sure appreciate it.

Please answer to my OSU E-Mail address, since I may not look here very often.

Thanks,

Ang., W8EDR

> I want to drive it with 1 watt but my rig does not produce that .
> To cut a long story short is it possible to attenuate the signal
> between the transceiver and amp down 1 watt .
> Any suggestions/comments will be gratefully received.
> Stephen G7UXL
==========
Stephen , You can easily construct a 5dB attenuator by means of 3pcs
2 Watt carbon composition - or metal film resistors in a small metal
container eg aluminium cylinder packing (35 mm film roll) or in a
home made box from double sided PCB material. Keep the component
leads of minimal length,just to solder them together. In the PI
configuration the 2 resistors across signal input and signal output
are 200 Ohms ; the 3rd resistor between in- and output is 33 Ohms.
With this attennuator, 5 Watts is reduced to about 1.5 Watts which
(if the poweramp input/ouput transfer is linear over its range) will
give you an output to the feeder of about 60 Watts.
The above attenuator is based on 50 Ohms input /output impedence.

Although a standard resistor is 220 Ohms ,you might be able to select
a low value from a 10 percent accuracy batch. The value won't be all
that critical for this application.
If you can find some 2 Watts carbon-composition resistors of 180 Ohms
or about ,you could try to remove bit by bit with a grinding stone
,checking the resistance frequently as the resistor value increases.
Success !

393. Got my audio tube cathode follower grid negative, in CD player

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-15 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDw6w3A.4po@netcom.com>
Source record: 103270

Posted about my bafflement of why I was getting positive grid to cathode voltage bias in a cathode follower tube circuit. Someone (thank you) e-mailed a suggestion that the amount of plate current I was passing would make the grid bias do this. So I increased the cathode resistance from 1K to 10K, and used a bench power supply to find a suitable bias voltage for the grid, so I would get a decent output on the cathode. The audio amplitude is around 4V p-p. Now the plate current is about 1/2 mA, and the grid sits about 0.2V below the cathode. And only a few microamps of grid current.

Sounds pretty good. I have a test CD, and played an intermodulation test tones track, and it seems clean.

Find a picture and diagram of this in alt.binaries.pictures.misc & 12hr

I found this hard to believe - that the one agency that should monitor
for CW distress signals doesn't. I called the USCG monitoring station
in Point Reyes, CA., and confirmed that they do not.

I wonder if CW will be dead after this generation, like landline morse?

You may try to locate your radio farther away from your computer. Also try to turn the radio for maximum pick-up of the station and minimum pick-up of the noise from the computer.If you are an electronics expe-rimenter, I can suggest an idea, but you will have to open your radio and do a little bit of extras. >_didn't_ cause it.

Well, I just lost my mother 2 months ago to breast cancer. She was not a ham, and you could not get her to even pick up a mic. It came on suddenly and ended suddenly. Started with a small lump in Jan 95, ended in death June 96. Cancer isn't funny, nor is blaming something for causing it without proof.

I saw what my mother went through, and wouldn't wish that on anyone. I hope you have much better luck, which I'm sure you will.

Perhaps the use of an HT helped keep the cancer cells at lower level than they would have been without it?

Just a thought.

Take care..

Nice try guys, but I might wait a while before starting construction of that
favorite "look alike" antenna. This one is DEFINITELY going to end up in
court as has been discussed on several broadcasting list severs because the
FCC is trying to preempt deed restrictions and every homeowners association
is against this. Just waiting for the fireworks to begin.

399. READ THIS NOW!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-15 00:00:00 UTC
From: pmcdaddy@usit.net
Message-ID: <4v18h4$l35@news.usit.net>
Source record: 103276

Turn a measly $5 into $50,000!

Taking 5 minutes to read this text may be one of the best decisions you

ever made.

I could make $50 000 within 4 weeks for an investment of only $5. I

thought it was a huge joke! I spoke to my friends about it

and they thought likewise. But after three days of desperate struggle

I decided I had nothing to lose.

My family and I sent $1 by snail mail to each of 5 names and addresses

specified in the article. We then

placed our own name and address in the article and posted it in 200

other newsgroups.

Two weeks later, I started receiving money in the mail! I could not

believe it! Hundreds of dollars turned into thousands, and in the 4

weeks,

I received a total of $53,654. It came from all over the world.

If you follow the 3 steps below, there is no reason whatsoever why the

same shouldn't happen to you. This is a perfectly legitimate investment

opportunity. You invest $5 and you receive a return on your investment.

So does the next investor. NOT ILLEGAL, NOT A CHAIN LETTER - PERFECTLY

LEGITIMATE!

OBVIOUSLY, IF YOU ARE NOT INTERESTED, THEN DON'T PARTICIPATE. BUT

PLEASE

PRINT THIS ARTICLE AND GIVE IT TO SOMEONE WHO MAY WISH TO TAKE

ADVANTAGE.

The procedure is very simple.

STEP 1. Write your name and address on 5 separate pieces of paper with

the words "PLEASE ADD ME TO YOUR MAILING LIST". Fold a $1 note or money

order or bank draft in each of the pieces of paper and mail them to the

following five addresses:

****

1. Qunwei Yu, 11405 Tiverton Court , St.Louis, MO 63146

2. Nat Heatwole, 7550 Damascus Rd., Gaithersburg, MD 20882

3. Jeff Katz, 7 Seir Hill Rd, #41, Norwalk, CT 06850

4. Eric Johnson 14817 Holden Circle, Horizon TX, 79927

5. Patrick McElroy 818 Hollow Creek Dr. Newbern, TN. 38059

****

STEP 2. Now remove the 1st name on the list, move the other 4 names up

(5 becomes 4, 4 becomes 3 etc) and put your name and address as number

5 on the list. You can do this by re-typing this article or simply

editing and re-posting it in this or another newsgroup.

STEP 3. Post your amended article to at least 200 new groups (there are

17 000 of them).

You are now in the Mail Order Investment Business and you will start

receiving $1 returns by mail within a week or two. The more newsgroups

you post to, the bigger your return will be. You may want to rent a

Post

Office Box to handle the volume of mail you are likely to receive.

If you wish to remain anonymous, you can use a pseudonym such as

"The Manager" or "The Investor", but make sure your address is correct!

NOW LET ME TELL YOU WHY THIS SYSTEM WORKS!

Of every 200 postings I made, I received an average of 5 replies, YES -

ONLY 5, each with a $1 bill enclosed. You make $5 for every 200

postings WITH YOUR NAME AT NUMBER 5.

Each person who sent you $1, now also makes let's say,only 200

additional postings WITH YOUR NAME AT NUMBER 4, i.e. 1000 postings.

On average therefore, 50 people will send you $1 with your name at

number 4. You make $50.

Your 50 new agents make 200 posting each WITH YOUR NAME AT NUMBER 3

or 10 000 postings - average return 500 at $1 each is $500. They

make 200 postings each WITH YOUR NAME AT NUMBER 2 = 100 000 postings

= 5 000 returns at $1 each = $5 000.

Finally, 5 000 people make 200 postings each WITH YOUR NAME AT NUMBER 1

and you get a return of $50 000 before you name drops off the list.

AND THAT'S IF EVERYONE DOWN THE LINE ONLY MAKES 200 POSTINGS! Total

income in one cycle = $55 500.

From time to time, when your name is no longer on the list, you take

the latest posting that is appearing in the newsgroups, SEND OUT

ANOTHER $5 TO THE NAMES THAT ARE ON THE LIST, PUT YOUR NAME IN

AT NUMBER 5 AND START POSTING AGAIN. Remember, 200 postings is only

a guideline. The more you post, the greater the return.

Let's review the reasons why you should do this: THE ONLY COST FACTORS

ARE 5 STAMPS, 5 ENVELOPES, AND 5 $1 BILLS. Anyone can afford five

dollars to put into such an effortless investment with SPECTACULAR

RETURNS.

Some people have said to me "What happens if the scheme is 'played

out' and no one sends me any money"? Big deal! So you lose $5 - but

what are the chances of that happening?

Do you realise how many Internet Users there are? Do you realise how

many times this scheme can be utilised over and over again - with COMPLETELY NEW people participating?

There are not HUNDREDS, NOT EVEN THOUSANDS, BUT HUNDREDS OF THOUSANDS OF NEW INTERNET USERS EVERY MONTH!

Remember, read the instructions carefully and play FAIRLY...that's the only way this will work. Get a printout so you can refer back to this article easily.

Try to keep a list of everyone that sends you money and always keep an eye on the newsgroup postings to make sure everyone is playing fairly. You know where your name should be.

>-recommend in industrial situations?

Hi Dave,

I have work in a couple of machine shops where lead was handled and worked. If you are just moving a piece of lead from place to place by hand you have to wear gloves and coveralls which must be properly diposed of. When machining lead you must wear gloves, coveralls, and a respirator. Given all this I think I would keep the solder out of my mouth. It always has a layer of lead oxide (poison) on the outside. It would also probalbly be a good idea to wear gloves like surgical gloves or something similar. Having said all that I also ask my doctor about lead levels in the body because I had noticed some lead testing being done a my place of employment. He said that if I had had dangerous lead exposure that there would be noticable symptoms. I suppose that the symptoms might be mistake for something else, but at least it is nice to know there is a warning of some kind before you keel over. If it was me I think I would keep the stuff out of my mouth and at the very least wash my hands real well after each session.

Hold the iron in your mouth. :-)

Check QST, March '95. It has a very simple interface circuit. I've
built this circuit and it works great.

Also if you want to write your own programs to control the radio, Icom's
control codes are available on the Web, but I forget where I found them.

Brian,
If you contact Mr. Dean Kidd (W7TYR), He can supply you with
just about any manual you want. If you can find a copy of the book by
Stan Griffiths called Oscilloscopes, selecting and restoring a classic,
you will find his address and telephone number in the back. This book is
all about tektronix oscilloscopes(vacumm tube types).

I have considered building my own 6 meter R/C equipment but haven't been able to justify the cost and time required when a commercial 4 channel unit is available for as little as $140 w/rx and tx, nicads, and three servos. BTW the rx is double conversion. Check out the Futaba Conquest if interested. I can't come close to duplicating it for the price.

Here in the UK, British Telecom ship-to-shore stations stopped
monitoring 500 kHz last year and I believe Portishead Radio (who handle
long-distance HF communications to shipping) has also largely ceased CW
operations, although they still ID in CW on their SITOR circuits.

BT have also handed over their 2182 kHz R/T distress watch to the
Coastguard Agency who had only covered VHF CH16 until then. I worked for
a while recently as a volunteer assistant at our local CG SAR centre and
although there were several experienced CW operators there they had
learned the code in the military. It seems there is no longer a CW
requirement for persons wishing to become Coastguards in the UK.
>
>
>I wonder if CW will be dead after this generation, like landline morse?

I hope not, it will always have an application somewhere in radio I
think, even if only to ID other systems, but I think things like NAVTEX
and DSC will totally replace it in the Maritime Mobile Service.

416. Question abt Push-pull RF Amplifier plate tank circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-16 00:00:00 UTC
From: hipiket@aol.com
Message-ID: <4v2o53$nbt@newsbf02.news.aol.com>
Source record: 103196

I'm planning to build an RF amplifier using two tubes in push-pull and I have a question about the tank circuit.
I've noticed that every design I have seen from the 1930's to the 60's ARRL handbook has an RF choke at the center-tap of the tank coil, where the B+ is applied to the circuit.
Why is this? When one tube is in conduction and that end of the plate coil is approaching zero, the other end will be near two times B+, but the center tap should always be at B+ but have no RF at that point.
Why can't I just use a feedthrough capacitor and a short lead to the coil center-tap and dispense with the RFC?
Thanks for any ideas...de AC4AQ (Jeff).

>
>

It varies with the particular circuit used Claude. The grid dissipation is a function of the average voltage difference and current between the grid and cathode.

It is also a function of short term duty cycle with a large grid like the 3-500Z uses.

The tube would be very safe below 150 mA in most AB2 circuits on single tone carrier. On SSB with a conventional meter movement the grid current should show a very low value, perhaps 20 -50 mA, the danger here is flat topping and distortion...not dissipation.

The grid is VERY rugged in the 3-500. The tubes are much more subject to gas failures and mechanical failures than operational related problems, unless you melt the anode or glass.

Really? Documentation, please? Everything I've ever seen indicates the only hazard is the irritation factor of the smoke, and not washing the lead off your hands...

BTW, your safety precautions indicate that the opposite is true - no way the EPA and OSHA would ever allow you to merely blow toxic fumes across the room with a fan.

Hi Jeff,

You can use a coil that is "RF grounded" at the center, but then you should float the rotor of the tuning capacitor for RF.

You don't want two conflicting tuned circuits to be created, with each half of the coil and each half of the air variable potentially tuned to different frequencies by stray effects and component tolerances.

It is generally considered safer to float the coil center and RF ground the rotor of the tuning cap, because the though is that gives better high order harmonic suppression.

There is no reason in the world to use a 2.5 mH choke though, that value is much too high and can lead to VLF parasitics. A few hundred micro-henrys with a high value resistor across it would be a better choice for the center of the coil at HF.

Yes, except for those who use it for nostalgic reasons. It is no longer cost effective when VLSI chips are so cheap, and it no longer holds an edge in weak signal work when more competent coherent modulations with strong codings are possible. We've been able to copy such signals well below the audible threshold for years, or when there's a good SNR, at speeds far in excess of what a Morse operator can handle, but the equipment to do it was too large and too expensive. That's all changed now. It is just another chip or two in an already VLSI filled radio system.

Just as the vinyl LP virtually disappeared with the advent of the CD, OOK Morse will disappear in favor of more robust coherent digital modulations and codings, except where regulatory inertia makes it hang on for a while longer. The LP to CD transition points out something else too. While the LP turntable appears simple in concept, to get good fidelity required very expensive high precision in the turntable and the cartridge. OTOH, CD players with better fidelity are commodity items, hung from the neck by a strap, substituting cheap silicon and strong coding for precision mechanisms and stable bases. A $70 CD player sounds better than a $500 turntable and cartridge. The desired signal gets through better because the encoding is so much better that channel impairments are much less of a problem.

The same thing is true on the radio channel. Strong coding can make up for even severe channel impairments. This sort of robustness is exactly what we need in a distress signalling system. It also works to our benefit in more routine usages, allowing us to use less power and occupy less spectrum capacity than more archaic methods. The switch to stronger digital codings is at least as dramatic as the switch from spark to CW in the benefits it brings to us.

And just as there was resistance to the change from spark, there will be those who resist the changeover from OOK Morse to better digital modulations and codings. Hopefully this time it won't

require regulations banning the more archaic form to force the changeover. It makes me mildly unhappy that I can't play with a modulated arc transmitter just for the hell of it, and I suppose it would make Morse lovers unhappy if they couldn't play with their hand and ear methods just for the hell of it too.

> The opinions expressed in this message are my own personal views
> and do not reflect the official views of Microsoft Corporation.Hi,

I did made a few years ago a 11 meter transceiver to 10 meter. First i change the pll clock x-tal into 10,24Mhz. Then i use a other x-tal for like 10.50 for going up to 10 meterband. This was working on a FM transmitter. I did used it only for receiving.

For going to 2 and 70cm you can use a transverter, take a look in the magazine's for a shop.

good luck with it.

Hi there Eric, well I guess the best place to start is the ARRL Handbook, this is a goldmine of information on not just circuits, but the construction techniques that are very important once you start to move away from the lower frequency areas of the amateur bands.

Maybe there is a local radio club that can also offer you some assistance and arm you with the skills you will need as your amateur radio career advances.

Good luck to you - who knows I might work you on 10-FM when the band starts to rise again.

You are experiencing RFI (aka EMI). It is likely ac magnetic radiation from your CRT yoke. Consider that the ferrite antenna coil of your AM radio is coupling to the deflection coils of your PC CRT. Since EM coupling diminishes as the cube of the distance, and also is angle sensitive, you can minimize this sound interference by trying many locations and orientations of the am radio. You will find some locations that maximize signal (station) to noise (PC CRT), and that's where you park your little AM radio!

426. Re: Question abt Push-pull RF Amplifier plate tank circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-17 00:00:00 UTC
From: Clifford Buttschardt <cbuttsch@slonet.org>
Message-ID: <Pine.GSO.3.95.960817131620.6518A-100000@spork.callamer.com>
Source record: 103206

Jeff and the group. This is a very old question and I guess only an oldie can answer it. In any push-pull tank coil and split stator arrangement there is two ways in which the ground can be accomplished. Either ground the split stator rotor or RF ground the center of the coil BUT NOT BOTH! One way to visualize this is as two separate single tuned circuits magnetically coupled. Now you can see why both capacitor and coil should not be grounded as they will be fighting each other for proper balance. Therefore, if the center of the capacitor is grounded, an RF choke in the center of the coil should not have a bypass. If the center of the coil is bypassed to ground, then the capacitor need not be split stator at all since there is no need for a capacitor ground! Of course, the tuning capacitor often is split stator. Be careful here as one can get into difficulty with high voltage on the tuning knob either permanently or when the capacitor flashes over! Check out the Grove Scanner Beam. I've got one and it looks just like a TV
antenna except it's mounted vertically instead of horizontally. I know
your able to TX on 2m with it. I've used it that way and the manual says
you can TX with it using up to 25W.

>solder or un-solder some microsized surface mount part or something. I
>therefore breath a lot of solder/rosin smoke. Is this bad for your health?
>Is there lead in the smoke?

There shouldn't be any lead vapor in the smoke. Soldering temperatures
are well below the vaporization point of lead. There will be rosin fumes,
however, and they can irritate the eyes and lungs. Use a fan to keep the
fumes out of your face. I keep an ordinary 12 volt boxer fan on the
bench for this. There are commercial fume extractors available, but
the simple fan is usually sufficient.

The big lead danger is that some will rub off on your fingers while
you are handling the solder. This can then be ingested if you eat,
drink, smoke, or otherwise touch body openings without washing your
hands carefully first. Don't rub your eyes either. Obviously, don't
pull the old stunt of holding the solder in your mouth while you work.

>All uplinks are required to do this.
>(commercial)

No. We're required to encode our call sign in the vertical blanking interval in such a way that rolling the sync bar down allows it to be read off the monitor. Or we can use a specified digital encoding in the vertical interval instead (this has become the most common method and is more adaptable to automatic computer control of networks of uplink systems). We *cannot* use OOK because that would change the transponder saturation level and would cause interference to other signals being relayed.

Commercial satellite transponders are operated with a specified saturation level. When we power up, the satellite control center will advise us to increase power until we reach the specified saturation level, and then hold it there so that we won't pump other signals using the transponder. (We watch that on the downlink spectrum analyzer in the truck anyway, but satellite control has the final word.)

We can't use MCW on one of the sound subcarriers for the legal reason that we must continously ID our uplink signal (so that a source of double illumination can be identified immediately), and for the practical reason that we're using the subcarriers for program audio anyway.

I'm not familiar with the ID requirements of SCPC or other data uplink systems, but they can't use OOK either, and I would opine that they embed their ID in the data framing (somewhat similar to amateur packet).

Ah, this explains a lot. :-)

Actually, the effect of lead poisoning is not insanity (that's the
result of mercury poisoning, IE Mad Hatter syndrome). The mental
effect of lead poisoning is a marked lowering of IQ. This is well
documented, and the microgram per liter concentrations required to
have a measurable effect are tiny, less than 5 ug/l. That's why all
the concern about leaded gasoline and leaded paint and lead bearing
solder in water piping.

Putting solder in your mouth is dumb, and makes you dumber.

The best way to make a repeater is to start with a surplus commercial
radio such as a Motorola Micor or GE Mastr II (or Exec II). Most
amateur repeaters are based on one or the other of these radios.
The conversion instructions are widely available, and easy to perform.
If you prefer to build radios from kits, Hamtronics has receiver and
exciter kits for sale which can be used. Converting one of the commercial
radios is cheaper, faster, easier, and will result in better performance
however. The most time consuming part of this part of the project will
be waiting for the channel crystals you'll have to order to come in.

You also need a duplexer. Building one of these is challenging, but
there are a number of them available on the surplus market which you
only have to retune to the amateur band. For a low power repeater on
a benign site, a simple notch duplexer will work. For higher powered
repeaters, and repeaters located at high RF sites, a pass/reject
duplexer is preferred. These latter are more expensive and harder
to find surplus.

There have been a few articles in the amateur literature on building
your own duplexer, but this is not usually either easy or cheap. You'll
need metalworking skills, a source of large diameter copper pipe, a
source of finger stock, the ability to torch solder, and you'll need
to understand a good bit about RF field behavior in cavity resonators.

Controllers are usually based on simple embedded microprocessors today,
though you can still do a simple controller in discrete logic. While
most amateurs purchase their controllers, any micro from the venerable
KIM-1 to a PC can be used as the basis for a controller. Stifling the

RFI emitted from micros not intended for repeater service will take
the bulk of your time in this area if you don't opt to buy a purpose
built repeater controller.

With all the parts on hand, and suitable RF instrumentation available,
a repeater can be assembled and tested over a weekend. Most of your
time is consumed hunting down the materials to build the repeater.

>pools is a fall out of the freedom of information acts...

That's right. Ameco and the ARRL had Q&A study guides in the 50s, and before.
There were also Q&A manuals for commercial license exams well before 1960.
The only difference with Bash was that his books tried to have actual word
for word questions from *current* exams rather than questions from expired
exams (which were freely available and used by the other publishers to prepare
their Q&A manuals).

Bash paid people who took the test to write down the questions and answers
from memory right after they left the exam session. (I think he paid something
like a dollar a question.) And he published updates frequently, unlike the
ARRL, who hardly ever revised their Q&A manuals.

The ARRL license manuals weren't exact word for word from current exams
because the ARRL didn't pay anyone to gather their material from exam
sessions. This made the Bash books more useful, and they cut into the
sales of ARRL License manuals. This caused a howl from Newington because
Bash was getting into their back pockets. When FOIA made the pools public,
and the VEC system started, Bash lost his competitive advantage, and couldn't
compete with a major publishing company like the ARRL (who were creating the
questions for the exams), so his books disappeared.

What made the Bash books useful was that the FCC only used 4 different
exams at any given time. That sharply limited the number of questions
whose answers needed to be learned. With the publication of the entire
question pools, and the ability to generate exams drawn from the pool
at random by computer as needed, the applicant now has to learn the
answers to all the questions in the pool instead of just the ones on
a limited set of exams in use.

The FAA went this route (publishing the question pool) with their pilot
written exams long before the FCC did. It makes the student learn more
material than just what may be on a particular exam.

>start making the measurements.

The official limit is based on NCRP 86 and ANSI C95.1-1992.
You are correct that people with indoor antennas are probably
in somewhat of a bind. However, don't forget that the standard
requires a 6 minute *average* for controlled exposures and a 30
minute *average* for uncontrolled exposures. Given the duty cycle
of typical amateur operations, this is an escape clause for many
amateurs. Old timer AM operators who talk 10 minutes at a stretch
with their plate modulated kilowatts are in trouble, but the average
SSB operator probably doesn't have a high enough duty cycle to break
the limit *on average*, first due to the peak to average power
ratio of SSB, and second due to the quicker back and forth nature
of the conversations typically held on SSB.

I've compared the calculated exposures I posted earlier with the
FCC measurements made at a number of amateur stations. My calculations
seem to give distance numbers that are about 30% pesimistic compared to
the FCC's actual measurements. (Of course my assumptions for those
calculations were intended to be conservative.) But that's encouraging.
The FCC only found stations breaking the limits when they used ground

mounted verticals, open wire fed flattops, and a quarterwave whip
on a car.

I think Sumner's contention is for the most part correct. High
power AMers and RTTY operators may have something to fear, but
most of us are going to squeak through. I'm more concerned about
what this is going to mean for access to good repeater sites.
We're dealing with combined exposures here, and the fields
could be very high, and with a high duty cycle. This may
affect maintenance access to sites in such a way that amateurs
may be denied access simply because it would be too inconvienent
to the paying customers if they had to shut down while work
was done at the site. "Moonsuits" may be an answer, but I don't
relish having to wear one of those on the tower.

>
>Rob Neff (N7ORY)

There is a chart. It is on page 96 of the report and order. It shows the controlled exposure power density in the 10m band to be 900/f, or about 30 mW/cm^2, and the uncontrolled exposure to be 180/f, or about 6 mW/cm^2.

Now to get down to that level, the RF field from a 100 watt isotropic source would have to expand to a sphere of surface area 100 watts/.03 watts/cm^2, or 3333.33 square centimeters. The formula for the surface area of a sphere is A=4*pi*R^2. We know A and want R, so we rearrange the formula to R=sqrt(A/(4*pi)). That gives a value for R of 16.29 centimeters. So, if no part of your antenna comes within 16.29 centimeters of you or your immediate family, you're Ok for power density.

You can repeat the calculation for uncontrolled exposure by using 6 mW/cm^2 instead. That's an area of 16666.67 square centimeters and a R of 36.42 centimeters. So if no member of the public can approach any point on your antenna closer than 36.42 cm, you're Ok on power density.

Note, since your antenna is not an isotropic source, this is a conservative calculation. Actual exposure will be less since all of your power won't be concentrated in the single point on the antenna closest to you. To get the real value, which will be lower, you'll have to use an antenna modeling program. However, since the safe distance is so short, that shouldn't be necessary.

Note also that a gain antenna will have different safe distances in different directions. You'll need more detailed calculations to determine actual safe distances with a gain antenna. In every direction except the axis of the main lobe, the safe distance will be less than for the isotropic case (disregarding strong sidelobes). In the main lobe, the safe distance will be greater than for the isotropic case.

Ok, now we need to look at the magnetic field exposure. For
10m, the limit is 4.89/f or 0.163 A/m for controlled exposures.
To calculate *far field* exposures, we note that the impedance of
free space is 377 ohms. P=I^2*R, so the power density in watts/meter^2
to express a current of 0.163 A/m is 0.163^2*377 or 10 watts/meter^2.
We can plug that into the first calculation like this,

100 watts/10 watts/m^2 = 10 m^2.

That's our A. We can now use R = sqrt(A/(4*pi)) and find that we
need to be at least 0.89 meter from the antenna to be within the
controlled exposure limit. But note that 0.89 meter is *not* in
the far field of the antenna.

The uncontrolled exposure limit for 10m is 0.073, so the minimum
safe distance for the general public is 2 meters. But note that
2 meters is *not* in the far field for a 10m signal.

(Rule of thumb, far field calculations are only valid when you're at
least 10 wavelengths from the antenna.)

The third limit is the electric field strength in volts/meter. For
10m, the limit for a controlled exposure is 1842/f or 61.4 volts/meter.
The impedance of free space is 377 ohms. P=E^2/R, so the power density
in watts/meter^2 needed to express 61.4 volts/meter across 377 ohms is
61.4^2/377 or 10 watts/meter^2. We can plug that into the first calculation
like this, 100 watts/10 watts/m^2 = 10 m^2. That's our A. We can now use
R = sqrt(A/(4*pi)) and find that we need to be 0.89 meter from the
antenna to be within the controlled exposure limit.

I'll leave the uncontrolled exposure limit as an exercise. All you
need to know is that the limit is 824/f. (Actually, all you need
to notice is that the safe distance for the electric field is the
same as for the magnetic field.)

But note again that this is only valid in the *far field*.

Because the safe distances we're getting here for the far field assumptions
are *not in the far field*, there are near field discrepencies not accounted
for. These can be serious as we'll see below.

For example, the Rrad of a dipole is roughly 50 ohms (would be 73 ohms
in free space). At 100 watts, that gives a feedpoint current of 1.414
amperes. The magnetic field declines inversely with distance in the
near field (not the inverse square as is the case for power). So 1.414/0.163
= 8.67 meters. That's the near field safe distance from the current node
in the antenna for the controlled magnetic field exposure. For the
uncontrolled exposure, the minimum safe distance is 19.8 meters. Similarly,
for the electric field, the safe distances are the same, but from the
antenna voltage nodes (the ends for a dipole) instead of the feedpoint.

Now that places the safe distance at about 66 feet for the general
public. That's very different from the 2 meter safe distance we got
with far field assumptions. So why show the far field calculations?

Because at VHF/UHF where the far field is a comparatively short physical distance from the antenna, and where exposure limits are much tighter, the far field values can dominate, especially in the gain antenna case. You need to run both sets of numbers. If the far field numbers actually fall in the far field, use them. Otherwise use the near field numbers.

Note that at HF, particularly lower HF, the near field magnetic field numbers are the ones of concern. It is possible to measure this magnetic field directly with a fairly simple instrument. You should do this to find and map any hot spots. At VHF+, there is no reliable instrument to measure the magnetic near field. Electric field measurements can be done instead since they'll work out to the same distance (except from the element ends instead of their centers). This isn't quite as easy to do, however, because there are more potential sources of error in this measurement. But direct power density readings also become possible at UHF+, and relatively simple instruments can be used to do that to a fairly high degree of confidence. Once you have any one of these numbers, you can derive the others at least to an outer bound.

>battery packs!

There is documented evidence that exposures of greater than 10 mW/cm^2
can cause harm. In particular, cataracts or loss of focal flexibility
due to RF heating of the lens of the eye, and in some cases cancers.
Just as some people get away with smoking cigarettes for years without
getting lung cancer, some people can get away with excess RF exposures
for years without apparent harm. But statistically, the rate of cancers
does increase with exposure in large populations. Milham found a doubling
of cancer rates (compared to the rates of the general population) for some
cancers in his study of deceased amateurs.

The frequencies where (RF heating) exposures are most harmful to humans
are in the range 30-300 MHz. That's why the standards require a lower
exposure at those frequencies than at lower or higher frequencies. The
reason for that is those frequencies are the ones which couple most
strongly to the human body. That doesn't mean we can treat exposures

at other frequencies casually, but the evidence does indicate that higher or lower frequencies don't couple as strongly to the body. Therefore a higher exposure limit for them is tolerable.

The new MPE is 1 mW/cm^2 in the 30-300 MHz region. That gives at least a 10x safety margin (actually, the margin is probably greater than that since 10 mW/cm^2 is about the lower bound for noticable RF heating effects). At 100 mW/cm^2 and higher, however, effects can be very noticable very quickly. There are documented cases of amateurs being blinded by such exposures, literally overnight. (There is also industry evidence, in particular the IBEW has a case file on this.)

Athermal effects, IE effects which aren't a result of RF heating, are a bit more questionable. There are population studies which go either way on this. If there are effects, they appear to either have a weak statistical association, or have to be coupled with an as yet unidentified co-factor. Something appears to happen in some people, but the mechanism isn't understood yet. Athermal effects have been most noticed at lower frequencies, particularly when those frequencies are pulsed at a low rate, IE in amateur radio that would correspond to OOK Morse style signals. In vitro studies have shown changes at the cellular level when exposed to fairly weak pulsed RF fields. In particular, pulse rates in the 5-10 pps range have been shown to cause abnormal chromosome division. This is usually taken as an indication of a cancer causing agent at work.

>Rosin's bad for you too.

There *shouldn't* be any lead vapor in the smoke. Electronic soldering
temperatures are well below the boiling point of lead. However, the
rosin fumes are irritating and should be vented. About the only way
you'd risk lead vapor exposure is if you are torch soldering. Then the
temperature would be high enough to vaporize some of the lead.

The main method of lead contamination occurs from *handling* solder.
Some lead rubs off on the hands and can be transferred to food, or
directly into the body if you touch your mouth or eyes with contaminated
hands. Wash well with warm water before eating. Lead salts are soluable
in warm water (such as the water in your mouth, don't ever put solder
in your mouth).

Because lead salts are soluable in warm water, don't use water from
the hot water tap for drinking or cooking if you have lead soldered
copper water piping. Use water from the cold tap instead (temperature
makes an amazing difference in lead salt soluability). Or at least
let the hot water tap run for a while before using the water to avoid
lead concentrations in the stagnant water in the pipes. This latter
is the current EPA recomendation. There are now lead free solders
available for plumbing. (I'm dubious of plastic piping. I suspect
the plasticizer can escape into the water, and that stuff is a
known carcinogen.)

The decline of Rome is partially credited to their use of pure lead water
piping in the latter days of the Republic, IE the leadership got too stupid
to maintain their dominance. It's also why bootleg whiskey can get you if
the bootlegger uses old car radiators (lead soldered copper) as his

condenser. (The more likely reason bootleg will get you though is that unethical bootleggers will cut the brew with wood alcohol. That'll make you go blind. Be careful using methanol to clean solder flux residues.)

Lead poisoning is cuumulative, and lead can stay in the body for years. There are chelating agents doctors can treat you with to remove the lead, but you don't want to go through that. They make you sick as a dog, and they don't reverse the damage already done. OHSA recently required all our shop people be screened for lead exposure. All of us passed except one idiot who habitually snacked while he worked. His blood lead was 10 ug/l and he had to take the chelating treatments. Food is now banned from the shop, and anyone caught with solder in his mouth will be fired.

Your problem does not appear to be the result of a VSWR shutdown
circuit. It appears that the radio is not putting out full power
at any time. The power indicator on the rig is just a diode
sample of the voltage at the radio RF output connector. Since
detuning the antenna will cause a high VSWR on the line, and
with an appropriate line length the voltage maximum can appear
at the radio output connector, what you are seeing is just a
result of the detuning, and is not evidence of increased power
output from the radio.

To prove that to yourself, add some non-resonant length of
coax to the line and repeat your experiment. You'll find
the output indication of the rig changed from what you are
seeing now. The reason for that is that the changed line
length will no longer place the VSWR voltage maximum node
at the radio connector. By detuning the antenna a different
amount, you should be able to move the voltage node back
to the antenna connector and cause the output indicator
to peak again. But output power will not have changed.

The only way you can trust the output indicator to indicate
power output is if it is working into a 50 ohm non-reactive
load, IE a 1:1 VSWR.

Borrow a real power meter and measure the radio's output
power into a good dummy load. If it is below normal, you
may have a problem with the driver circuit, or with the
RF output module. Common module problems are an open
emitter in one of the output transistors, or an open
substrate in the module. It usually isn't practical to
repair these modules, so replacement would be in order.

OTOH, if a power meter shows full output into a dummy
load, the output indicator on the radio is merely out
of calibration. Note the indication which means full
power and live with it, or go in and figure out how
to recalibrate it.

It's never been about price or time with the homebrew bunch.

Check out the IC supply houses, I have seen a TX and RX chipset that provides all the encode/decode signals, you just need to add a transmitter and receiver. Sorry cant remeber where I've seen them but they were about $7.50 ea.

One of my co-workers let me borrow his copy of _In_Marconi's_ Footsteps:_Early_Radio_ by Peter R. Jensen. On the cover are four boxes and a picture of ol' Marconi in a pensive mood. I can identify every one of those boxes and I'm only 50 years old. Is there something wrong with me? Have I traveled back in time during an out-of-foot experience and now can remember being the radio operator on one of the Pharoah's yachts? Or did I just read _A_Boy's_First_Book_of_Radio_ from cover to cover sixteen zillion times so that I have everything mesmerized?

Seriously, though (yeah, right), Jensen's diagrams and schematics are interesting stuff to get people into making radios in wooden boxes again. Like the Marconi Wireless Telegraph Co.Ltd's "Type 16" crystal set on page 138. Like the guy in _ID4_ (which I refuse to see 'cause my medication won't let me) said: "I gotta get me one of these!" There's about six different knobs on this "Type 16," including a deal that evidently loose couples the antoona circuit into the rest of the LC stuff. Serious big time radio madness, this. Only problem: I gotta find someone with reasonable carpentry skills just to get the box made. (What? Me make it? You must be loony? Here, check out the stalactites where I spackled the ceiling in the garage...)

But I can dream... Maybe that's why the shack looks like a radioroom on a ship. Gotta replace the windows with port holes, for sure. But all the hoses and stuff... It's obtuse, man, obtuse. And those damn decorative maritime clocks that look like the ol' military ones what we had on the Saratoga (may she become refrigerator handles in peace), them suckers are expensive!

Whose got the address of the Crystal Set Society of America or whatever it's called? I need something to keep me from finishing the thesis.

Tom seems to imply that one or the other should be at r.f. ground. In my homebrew push-pull 4-400A, 50 mc. amp, neither is at r.f. ground. No connection at the rotor. RFC, 6 uH, at the coil. Working fine for 35 years! I don't know any theory, so except for the harmonic issue Tom mentioned (no problem here), I don't understand why one point or the other must be at r.f. ground. I hope Tom will explain it for us.

Let's see if I can guess. The RF choke has enough energy stored in its inductance that it acts as a constant-current source for the RF plate current pulses. The two tubes switch this current pulse back and forth, in the process energizing the flywheel tank. The DC supply re-supplies this energy to the choke. This works only for a balanced push-pull circuit. A single-ended circuit needs a ground reference point (a bypass capacitor).

I made an error here. I forgot to include the factor of 2*pi in the
above figures. That reduces the safe distance for controlled exposure
to just 1.38 meters, and for uncontrolled exposures to 3.15 meters.
That's much better.

452. Charging Help for 1.2 AH Sealed Lead-Acid Battery

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-18 00:00:00 UTC
From: schoon@cts.com
Message-ID: <4v5pq4$g2@newsfeed.cts.com>
Source record: 103225

Thanks for reading!

I purchase a small 1.2 AH lead acid battery, and would like
to ask for help in how to charge the thing. The sales guy where I
purchased it from said to charge at a current of 10% of the rated amp-hour
rating. OK, if that's true, then I need to charge at 120 mA. I would like
to be able to charge from a 20 amp, 13.8v regulated supply and my car.
I'v calculated the limiting resistor to be 12 ohms, using ohm's law.
When I figure in the power dissapation for the resistor, it works out
to be over 12 watts! Is this true??? Or would it all be easier to
get a low current, 12 volt wall wart and forget charging in the car?
I'm sure I've missed something, qould someone point me to the
right direction?

>Hi Rich, all 30 pages of the FCC text are to be found at URL:

>http://www.fcc.gov/Bureaus/Cable/Orders/fcc96328.txt

Thanks for the pointer. The regulation looks fairly ironclad to me. HOA's must allow TV antennas and 1m dishes. I think I will mail a copy of this to my HOA and get rid of the old cable monopoly I have been dealing with. At $30.00/mo., a TV antennas with mast and rotor will pay off very quickly!

>Lets all hope they extend this ruling to the Amateur Radio Service.

The legislation was driven by the type of economics thar we amateurs cannot muster. Also, with fewer people using cable, there could actually be more objections to amateur transmissions in these living quarters built in such close proximity. However, TVI and other interference concerns cannot be extected to improve when a law is issued giving free reign to most types of telecommunications. You can argue for a long time that you use your tribander antenna for TV reception (perhaps not the best reception) on the same antenna that you happen to transmit with. That's *if* anyone notices a difference between a TV antenna and a tribander (say a 10/15/20).
Anyways, it's something to try I guess ;)

>Good Luck with the HOA -- mine is hopeless.

I think after reading the regulation that your >HOA< is out of luck. You would have to have special circumstances affecting 'safety' (this would normally apply to tower hieght with respect to the closest adjacent residence, or possible zoning regulations for wind strength in some areas) or you would have to be in a historic district.

If your HOA does not believe the new regulation, or cannot undertsand it, it seems that you do not have to pay any penalties even if they 'fine' you. Like I say, it looks fairly ironclad but then again I am not a lawyer. I still think anyone having to live with one of these stupid antenna restrictions would be fairly safe going ahead and putting up a TV antenna...not much to lose, and a rather clear federal pre-emption to back you up.

Anything's possible -- ask Beck, Rife, or Lakhovsky. (OK, Beck -- the rest are dead.) But if EM radiation does have non-thermal biological effects, my guess is that at an arbitrary frequency and power level it would be more likely to harm than help.

Mark,

I am sure a lot of purists would suggest a better (and more expensive)
method, but I have charged many sealed lead acid batteries by putting
a series diode between the power supply (13.8V supply) and the battery
and just letting the battery charge at the rate it wants to. The diode
will drop the voltage to about 13V while protecting the regulating
circuit in your power supply in case you lose AC or someone turns
the power supply off. If you are worried about the battery drawing
higher than its rated charging current add a fuse or circuit breaker
between the battery and the charging source.

The phono input on most stereo amplifiers is designed for a very low input level. In addition, the phono preamp includes considerable frequency equalization that will make anything other than a magnetic cartridge sound terrible. Even if you could reduce the signal level of the sources you mentioned and use some form of "anti-equalization", the signal-to-noise would suffer considerably. In more than fifteen years in the audio biz, I never saw an adaptor of the type you want. Presumably, this is because it is cheaper simply to bypass the phono preamp altogether.

As a side note, a few very old (or very cheap) stereos were designed for ceramic phono cartridges. Due to the nature of ceramic cartridges, the stereos have no phono preamp or equalization, and will accept roughly the same input level as the "AUX" input on newer preamps.

If your stereo has an "AUX" input, that's the place to input signals from most external sources.

>I ain't at all sure this is right!!!!

I think Tom was referring to the fact that the coil will not
be exactly symmetrical around its center. If both the center
of the coil and the rotor of the tuning cap are grounded, the
actual inductance seen in the tank will change as the tubes
switch back and forth. This will cause the resonant frequency
of the tank to be slightly different, depending on which tube
is conducting.

> USB&LSB) carrier so normal CW scheme does not work - OOK in other

Actually John we want to use REAL CW on 2M to use the bottom
100 KHz of the 2M band! It is reserved for CW only and MCW
would not be allowed. There are people who do MCW here in Milwaukee
from time to time. On STREIGHT KEY NIGHT we actually use our
DTMF pads over one of our local repeaters and make MCW contacts
there.

But what we are trying to do is use that bottom 100 KHz, perhaps
build our own radios, use real CW, have fun and learn a lot
in the process.

465. How to remove scanner 800 MHz gap ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-19 00:00:00 UTC
From: arielbp@white.weizmann.ac.il
Message-ID: <1996Aug19.130223.18443@wisipc.weizmann.ac.il>
Source record: 103145

Hi everyone,

I have a small handheld scanner, the Radio Shack PRO-51. It has a gap in the are 823 to 850 MHz. I guess this is used for cellular phones in the US and illegal to have on a scanner. Around here, it is part of the 800 MHz public service band, and there is actually a local frequency within that range that I am very interested in receiving.

Has anyone had experience with modifying these units to remove the blocking of the 823-850 band ? I'd prefer to cut some jumpers, of course, but I can probably still find my way around a soldering iron (if I can just remember where I put my glasses...).

Would appreciate any help in this matter by email to:

arielbp@wisdom.weizmann.ac.il

>capacitor).

Isn't it simpler than that? There are actually three ground points, not two. The third one is the center-tap between the output capacitances of the two tubes, and that one is always grounded.

In Mark's situation the tube capacitances are providing the one-and-only center tap for the output circuit. That's just fine, so long as the output capacitances are large enough to swamp the out-of-balance strays. This is usually the case at VHF: the "Plumber's Special" and W1SL push-pull amplifiers work on the same principle.

In some situations you can get away with grounding either the tuning capacitor center-tap or the coil center-tap as well as the center-tap built into the tubes, without producing large circulating chassis currents between the grounding points; but the circuit is usually not symmetrical enough to allow you to ground all three.

That idea did occur to me also, but I am not sure that the tube plate to ground C is large enough, compared to the other circuit capacitances, to establish a credible ground return. The "cold" end of each tube's plate load impedance should return to its cathode with a low impedance path.

I get the feeling that without a well established ground return, the situation is rather messy and although it "works", it would not pass muster in any engineering organization.

My idea of the constant current RF choke doesn't sound very good, on second thought, and I withdraw it.

You would probably be better off, in terms of time and effort, just
buying a pair of 49MHz VOX headsets. I think Radio Shack still sells
them.

Good luck

No self denial. It would be irresponsible to keep quiet and bend over
for crap like this. They show proof that it harms, and how, then we
will worry about it. I thought we stopped using 'blood-letting' as a
treatment a long time ago, what they sugguest is the same thing.

'We don't know what it is, or if it is at all, but slit their rists
and let some blood out just in case.'

When did Part 97 start requiring people to use the lowest power setting all the time? I believe you're referring to 97.313(a), but you're apparently misreading it. 97.313(a) says "An amateur station must use the minimum transmitter power necessary to carry out the desired communications". There is a difference between 'minimum transmitter power' and 'minimum transmitter necessary to carry out the desired communications'.

I don't disagree that minimizing RF exposure is a good thing. I just don't agree with this reading of Part 97. Using the lowest power setting without regard to the ability to carry out communications might be considered 'liddish' by some ;-).

>the other must be at r.f. ground. I hope Tom will explain it for us.

It needs to be at RF ground because one half of push-pull resistances pulling on the tank are off during part of the cycle.

Look at a perfect case, drawn it out on paper.

If the tank truly floated at the center, and the center tap has infinite RF impedance through an RF choke, the tank would have no reference for the tube that was "on" fully since the entire rest of the tank would be "floating". Even the other tube would be "off".

The amplifier would not function at all if the center tap truly floated and the conduction angle of each tube was less than 180 degrees! We could not make the circuit work at all on any frequency. The low frequency analogy would be a push pull audio output output stage with the center tap fed through a very high reactance audio choke.

The circuit must provide an "RF reference to ground" in the tank for the circuit to work at all. For proper performance it should be the center.

The reference can be achieved "accidently" via always present circuit strays (capacitance from the plate circuit of the opposing tube---or tuning capacitor stray frame and rotor to chassis capacitance) will work, but doing it purposefully is almost always better.

Hi Eric,

A transverter that shifts RX/TX only by a small amount of frequency
is difficult do design, because you have to suppress the *image
frequency*. The common approach is to modify the 11m rig so that it works
on 10m.

Sti-Co is commercial antenna manufacturer that makes "disguised" antennas for police and other persons who want communications, but don't want to drill holes in their cars. The antennas usually are identical to the "stock" AM/FM antenna, but are tuned to the primary operating frequency range you intend to transmit on. It will also couple over to your AM/FM stereo with the use of a "BC adaptor" available from Antenna Specialists. Sti-Co's antennas are a bit pricey, but they are very effective. They also have duplexers and multicouplers available for using more than one transmitter. Check the communications magazines for their address. If you can't find it, e-mail me back and I will look it up for you.

478. Drake R4-C mods, filters, philosophy, etc.

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-19 00:00:00 UTC
From: zyx@aracnet.com
Message-ID: <zyx-1908961937560001@ppp-h50.aracnet.com>
Source record: 103158
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I purchased a set of Drake twins this last weekend (R4-C with very low serial and beautiful T4X), which has rekindled my long love-affair with these radios.

The T4X is very pretty (no corrosion on copper chassis!) and evidently desirable, as I had offers immediately after purchasing it. I assume it, as with the T4X-C, works wonderfully, with no mods ever being needed (unless you don't have the wierd thin mic connectors :)
I got both hand-held and desk-top mics with the thin connectors in the deal.

The R4-C is a different story. It is in beautiful mechanical condition, having little of the telltale chassis corrosion; and the rotary switches had little oxidation. However, it had the Sherwood first IF 600hz filter and relays, along with the Sherwood audio amp and power supply mods.

I have owned a number of R4-C's in the past, but none of them were the low serial number versions with the MOSFET 2nd mixer and other differences.

WHAT I AM WONDERING IS IF ANYONE HAS ANY ARTICLES OR REFERENCES DESCRIBING THE EVOLUTION OF THE R4-C, OR COMPENDIUMS OF MODIFICATIONS TO THE R4-C OVER THE YEARS*

In return, I offer my philosophy on modifications to the R4-C, based on years of experience as an owner of high serial # radios:

1. Do not use the solid state tubes that were sold in the 70's. Measurements done years ago showed they greatly compromised dynamic range. Moreover, there are better ways of lowering power consumption.

2. The only mods needed to the audio amp and power supply circuits is the addition of a 5k pot in series with the 3.3k R76. Adjust the bias voltage across the 0.82ohm R86 to 0.2v, or lower if only headphones are used. This simultaneously lowers audio amp quiescent current and permits much cooler operation in the power supply regulator and transformer. Also, more headroom is available for the power supply regulator to operate, also, providing less hum.

Then in the audio amp a 0.0027uf cap is connected in parallel with the 22k R83 and a 0.1uf cap connected in parallel with the 0.005uf C101 to limit freq response and hiss. These values aren't cast in stone, and can be increased or decreased depending upon the operator's preference. Note: that unlike the Sherwood boards, these mods are easily undone if needed for sale to some finicky person.

(The radio I bought had the Sherwood audio amp. It suffered from very high hiss, which I could not get rid of by attempts to bandlimit the amp's response along the lines of the National Semi LM393 apps data. Those National Semi high power TO220 amps like the LM383 and LM1893 are notorious for oscillating at HF frequencies- in fact National spent most of its apps engineering time getting a pc board layout that didn't oscillate and then tried to get everyone to use it. Finally, in frustration, I reconected the original Drake circuit with superior results.)

For DXers who use headphones mostly, the original class A circuit works the best.

3. If for some reason, hum is intractable or you want to use an LM7812 monolithic regulator to power the R4-C, connect the +10V and +11V lines to the +12V bus, and remove R115, R68, C165, R116, R117, CR14, C168, CR18, and CR19. Thus 2 more sources of heat are removed from the power supply board. Also, C166 and C167 are connected together at the cap so that current flows from the rectifiers to the cap, and then back to the regulator. Also, the center tap for the full wave rect is removed from the chassis and rewired directly to the can of C166/C167.

Then, hum is non-existant.

4. The original diode product detector may be worth replacing with a stronger, more balanced design- but the answer is not an MC1496- I've tried it, and it doesn't work any better.

5. I have no info or experience with third mixer solid state mods. What do others know???

I am also looking for a good source of aux freq coverage crystals. If anyone knows of the best potential deals on these from major crystal manufacturers I would appreciate any info.

I have recently come across hundreds of very high quality 10pole 3khz linear phase and 5 pole 250hz linear phase 5.2mhz crystal filters. I am considering using these along with new carrier osc and premix crystals as new first IF filters. I am also interested in designing and using 16 pole crystal ladder filters in the R4-C. The radio has too much gain, so it shouldn't be too hard to utilize even CW bandwidth filters in the radio with crystals with Q of 150k or so.

I am also investigating replacing the first mixer in the R4-C with a DMOS commutating mixer, keeping V2 as a gain stage. An SD5002 would be used.

I hope I might have spurred some renewed interest in R4-C!!!!!!

>will only hurt yourself, but coming on here and stating that to hundreds

Unfortunately, your emotionally charged arguement is all you have to
prove your point that regulation is needed to the level it has been
applied.

It would be much better if we could ignore the people who wanted
to pass laws based on ficticious or emotionally founded fantasies.

Every so often the government does that, goes out on a "jag". They take
some information that is normally quite emotionally charged and use
it to pass laws that far surpass the need.

A good example was the "fact" that 50,000 children a year are abducted
and we needed new laws to stem this tide. They passed a bunch of new
laws, citing the dopey figure, without ever considering that it was
a lie. The laws remain to show how harmful a well-meaning but terribly
misdirected group can do.

With the 2.5 watts my little HT puts out, I get into some of the
repeaters in the area marginaly, others not at all. With the 5 watt
pack, I get into most of them full-quieting, some of them marginaly.
I comply with part 97 in this respect.

When it comes to simplex use, it's a different story. With my Gp-9, I
can use the 30mw setting and make contacts in Mesa which is 30 miles
away. So my "KH2PZ incorrect" 2.5-5 watts is not necessary.
And to get right to it, there is no provision given, with respect to
the rule you mention, on any of these commercially available HTs to
comply. Think about it, if your power is adjusted in steps, and you
can operate with a lower output then that povided by the radio's
settings, are you in violation or not? It says minimum power
necessary, not minimum power setting on the radio.
And one other thing, I don't know what rock you live on, and whether
or not you have to deal with intermod, but squelch'es are used at a
high setting here in Metro Phoenix.

Don't make any assumptions as to my operating practices or proceedures, as I will (or would) not make any of yours. But it seems that when you are presented with reasonable debate, you resort to attacking the person and not the subject matter. Frankly, that in itself is not amateur like.

You mentioned part 97 at the end of your last post, mixed with the subject we *were* discussing. It appeared to me that you were implying that this EPA crap (which is now also part of 97) was the basis for you advising that HTs be held at arms length at minimum power. Thus accepting the regulation as being valid and worthwhile. I obviously disagree.

If you want to keep debating the issue, that's fine. But keep it on the level of subject and not assumptions. Ok?

I'm rehabbing a K2RIW parallel 4cx250 UHF kilowatt amp that I inherited from
an estate, with no power supply or cables.
2kv B+ was originally supplied via a Millen HV connector.
Anyone have a few of these just gathering dust?
(looking for 2 males and 1 female)
Anyone have any ideas for better alternatives?

Thanks
Joe - AA3GN

There's one piece of critical information missing from this thread.
PC power supplies regulate the 5V output. The 12V output is whatever it
is. For typical PC loads it all works out right.
If you try to run the 5V unloaded, there is not enough energy in the
core
to give full output on the 12V port.
So, you need a load resistor on the 5V output to make sure the 12V
supplies enough current for full load. You also need a load resistor
on the 12V output to insure it stays in regulation when the external
load
is off.

Hmmm, strange, 2.5 to 5 watts is only 3db. 3db is only 1/2 an S unit,
certainly not much if any practical difference.

To all Electronics Companies, Service Person-
nel, Webmasters & Hobbyists,

I am preparing a book tentatively titled "Sam's
Internet Guide to the Electronics Industry", to
be published by Howard W. Sams & Co. and PROMPT
Publications. The book will contain site add-
resses for electronics resources. Companies,
organizations and individual web creators are
encouraged to fill out a simple FORM at the ad-
dress below.
-----------------------------------------------
http://web.idirect.com/~ifx/book/
-----------------------------------------------
In addition, any electronics related addresses
or resources you run into while surfing please
let me know by filling out said form.

If you lack FORMS capability send an email with
the info below. I am especially interested in
sites offering simple electronics repair data,
service specs and hobbyist help-pages. Other
resources are more than welcome. Top Urls will
be printed in this directory and updated in
future issues.

>capacitor).
>
>Bill W0IYH

That could be true Bill.

If the choke were the sole component involved, the choke would store and release a lot of energy to the tank. It would have to be a very good choke or it quickly would become a very hot or perhaps an arcing choke.

It's hard to guess why a circuit that should not work very well actually does. I can think of at least three things that help.... stray capacitances from the center of the tank to ground, the choke being less than infinite impedance, the tubes stray capacitance to ground (that's a biggie).

The output capacitance of the tubes forms a center tapped capacitance in parallel with the tank that is grounded at the center! If the tubes have fairly low capacitive reactance compared to the tank capacitor values, that's enough right there.

By the way, this is a second valid reason to float the coil and ground the variable capacitor junction...but one that mainly applies at higher frequencies. The original question refered to HF tanks.

At VHF, tube output capacitance forms a center tapped capacitance across the tank, grounded at the center. If the builder uses a tank coil RF grounded at the center at VHF, he is really asking for multiple resonance problems.

491. Help: TR-7500 PLL Repair

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-20 00:00:00 UTC
From: Eric Grabowski <eric.grabowski@software.rockwell.com>
Message-ID: <3219C2BC.7993@software.rockwell.com>
Source record: 103035

I have a problem with the PLL circuit in my Kenwood TR-7500 two meter tranceiver that could best be described as a "tough dog".

At first the PLL would become unlocked on transmit, now it won't lock on receive either. I took it to a dealer for repair. He replaced the PLL chip, which didn't make any difference, and proclaimed the radio unfixable.

I have poked around the circuit with my DMM and TEK 465 scope. All the dc readings seem to be about right. The waveforms are hard to read because the vco frequency is above the limits of the scope and it's hard to get true readings because of common mode noise and the low-level of the signals.

At a local hamfest, a fellow ham mentioned that this was a rather common problem with Kenwoods of this vintage (circa 1978) and that the fix is pretty simple. He remembered that it involved diodes but didn't remember the particulars.

I was just wondering if anyone else has experienced this problem and knows how to resolve it?

I am the original owner of this radio and it worked great until this PLL problem appeared. If it's possible, I'd like to fix it.

: My idea of the constant current RF choke doesn't sound very good, on
: second thought, and I withdraw it.

For a practical use of a very similar circuit, have a look at what's used these days to drive cold-cathode fluorescent lamps, such as back lighting for LCD displays. Typically these are push-pull transformer coupled arrangements with a choke in the Vcc lead to the push-pull stage. The choke impedance is simply (more or less...) transformed by the transformer to effectively limit the current in the lamp while allowing large voltage to be developed to ignite the plasma in the lamp. A significant difference is that the lamp drivers generally (from the circuits I've seen) do not resonate the transformer as a tank. I believe the RF choke, as Bill seems to suggest above, will limit the available power and significantly raise the output impedance of the amplifier. Consider that if the tank is shorted, if only one tube is "on" at a time and there is some time when neither tube is on, you simply excite the choke at two times the amplifier input frequency (plus harmonics).

Solid-dielectric RG-8 is supposed to withstand 6 KV, so you could use a length of this -- with the warning that you need to use different connectors than the RF in and out use, and cover the HV cable with a marked orange jacket. This would be a good solution only if you buried the power supply in a cabinet or rack where nobody else could get to it. It's also a good answer for using up those really oddball HV RF connectors we seem to encounter occasionally.

I've seen some commercially built HF rigs that supplied B+ through a _banana jack_ but while this may be OK from a dielectric standpoint, it's inacceptable from a safety standpoint.

Unequal load at the anodes causes a similar problem. One valve (I mean
tube) is undercoupled and one is overcoupled by tank unbalance.

>> In push-pull grid circuits there are advantages in floating
>both the variable capacitor and the inductor, and grounding the circuit
>through a preset differential capacitor to balance out all the strays
>(two separate preset trimmers can be used instead).
>

Not always, and certainly not unless the circuit's shunt C is a very low
reactance compared to the grid impedance. :-) It's a problem of
impedances, and general "do it like this's" can get us in deep trouble.

For an example, look at the grid circuit of a push pull class amplifier
that draws grid current. It has widely varying impedances at the grids
that gets pretty low, and very high capacitive reactance at each outer end
to keep things equal (unless the tube is *very* large). In class C (or
AB2) grid circuit, we want the coil center to be used as the drive
reference. Mutual coupling helps solve the problem, giving each grid a
stiff source.

The designer had best look at the actual application closely to decide
what method is best...especially at VHF. At a low enough frequency, we can
throw out some general rules and the system will work.

The original question was HF. In that general case with small tubes (like
20 kW on down), a center tap reference at the grid inductor and a center
tap reference at the grounded rotor on the output tank variable would
almost always be best.

Ref: Environmental Impact Reports...

Over the years, we have noted that there is a group within the
Environmental Agencies that tends to go bananas! To acquire
funds to increase staffs, set up new departments, etc., these
groups will go to any lengths to stampede the people, members
of Congress, into a tizzy! This is all intentional...they do not
necessarily know that anything is wrong...not enough data,
not enought testing, etc.

Sad situation, in an Agency as important as this one, that we
have these "whackos" still embedded there. They need to
be purged, their agendas are not in line with the real world
needs of an Agency of this importance. Out, out with them!

Recently, the "hole" over the Antartic filled in...ozone
has returned...years ago, some "real-world" Nasa scientist
warned the "whackos" of the Environmental Agency
that their statements were premature and not substantiated
with known historical fact...nor was there sufficient historical
data to make such a statement....however, the "whackos"
message was widely spread by the "media"...it was pronounced
as "fact"...nothing could be further from the truth! We all remember
the hue and cry...the sky is falling..the sky is falling..disaster..
more funds..more funds! Sick situation..sick..sick!.

Leonard...

As I recall (it's been too many years to be sure) FM is subject to what
used to be called the "thershold effect" where a small increase in
received signal will make a substantial difference in perceived noise.
This is what gives rise to the "quieting" effect mentioned by the
original poster - as in full quieting.

So, it seems your observation might be correct for someone running
SSB phone but not FM phone. Don't know about ACSSB.

>Therefore a higher exposure limit for them is tolerable.

I would much rather have a 20m antenna 10 yards from me, lit with
1.5kw then a 2.5gig magnetron at 750w. I wonder why microwave ovens
operate on the bands they do and not on 10m and 2m? And you say the
higher freqs are more subtle with regards to effect and heating? I
don't think so.

Always looking for a reason. All in the name of safety. Never any
proof. Statistics are not proof, they are an indicator.
You can get one set of stats from the media, and read something
completely different from the MMWRs from the CDC!
(Morbidity and Mortality Weekly Reports)

EXAMPLE:
Like the 'assault weapons' crap. You hear how they are the preferred
weapons of criminals, and used in the majority of deaths in the
country. Then you read the Governments OWN statistics, you find out
that 'assault weapons' contributed to about .8% of total gun violence
in the US. (Firearm inflicted injury, 1995)

>but the mechanism isn't understood yet. Athermal effects have been
>most noticed at lower frequencies, particularly when those frequencies

Oh no! An excuse to get rid of CW? (GAG)

>In particular, pulse rates in the 5-10 pps range have been shown
>to cause abnormal chromosome division. This is usually taken as an
>indication of a cancer causing agent at work.

Maybe this is the secret to evolution? If we didn't have small changes
in chromosomes, we probably would not exsist. And if we did, we would
probably all look exactly alike. I wonder what measurements are made
with respect to the amount of 'natural radioation' we receive on a
daily basis? The effects of cosmic rays on human development?

>(looking for 2 males and 1 female)
>Anyone have any ideas for better alternatives?

Yes!

Viewed from a country where separate B+ and B- connectors are not the
time-honored tradition, they look like a recipe for suicide if you
disconnect the wrong one first while the system is live.

Try MHV, or any similar coaxial connector that establishes a safety
ground *before* the HV connection is made, and keeps the ground until
after the HV disconnects.

I am wanting to build some 2 mtr/440 mhz dual band antennas and need some help. does anyone have info which describes how to build one using 450 ohm ladder line and in a J-pole configuration? I would like to enclose this in a piece of 3/4 or 1 inch pvc pipe to weather proof it and to give it some stability. also does anyone know the approx specifications that one could gain from an antenna like this? The configuration should have a so-239 connector in the end of the pvc pipe'

i am also interested in any other design (non ladder line) if it would still fit into pvc pipe.
please respond to me at tcmedlin@cris.com thanks, tom WA5KUB

A terribly misdirected group. May be so may not be so. Do you have any
facts to show that rf is harmless. Have you ever been in the near field
of a broadcast antenna at 1KW even. I have, not the facts or figures,
but by personal experiance know that the inner ears heats up at a
frequency of 1450 Khz and 1000 watts if you are there for any significant
period of time (ie. 30 minutes or so) Granted, amateur transmissions are
usually short, but would you like a 4 El beam being fed with 1.5Kw pep rf
pointed at your house???? I think not if it were your neighbors
antenna. Do not poo poo the harm that non-ionizing radiation may or may
not do. It is best to treat it with a little respect and use good
engineering practice at all times. Hey, a well meaning, but misdirected
group got a law passed because no one else has been able to prove them
wrong with hard facts and figures. I for one, after spending a few years
in the position of a chief broadcast engineer, treat an radiation,
non-ionizing or otherwise with respect. remember your microwave oven
operates in the middle of on ham band a about 1.2 gigahertz or so. And
it cooks things very swiftly. Agreed it is not 3.9 Khz or 7.2, but it
may be that the only differance is the power level and the exposer time??
who know for sure. I don't and have met few rf engineers that are sure.
Who wants to be the test dummy for this one fellows. Do I hear any takers?

>> in May 1993 QST.
>
>(reading the article now)

Kanga does offer kits for the R2 and T2, but they are simple enough
that you can dead bug them instead. I don't like the analog filtering
and phase shifter so I used an Analog Devices EZ-Kit instead. Do a
Hilbert transform on one channel and you have a perfect quadrature
shift. Filter as desired for the modulation waveform used.

For the quadrature phasing of the LO at 2m, a simple coax delay
line works fine. I use a 1/4-wave (electrical) piece of RG-174
coiled up and tucked in the box with the LO buffers. I use MAR-4s
as buffers on the in-phase and quadrature outputs going to the SBL-1s.
I'm using a signal generator as the LO, but you'd want to build your
own LO for a packaged unit. A crystal VXO should be fine to cover
just the CW segment of 2m.

Tight shielding, quality bypassing caps (ie: 500pf + .1uf + >10uf, and
ferrite choke in line should kill most noise.

Be sure your power supply includes minimum load resistor. Some may not.
If not, under light loading the supply could fall out of regulation.
Before hooking to $$ equipment, check voltage at all expected loads.

>..

The worst problem with them is a very subtle one that few people know about. When you take a lightning hit that raises or spikes your AC inbound supply lines and your supply lines go through one of these surge protector deals, you can have BIG time problems!

All switching power supplies that ride behind these surge suppressors with the MOV varistor avalanche devices have the potential to knee up the ground reference leg by about a 1 to 4 ratio of the input spike! Thus a 6000 volt spike that is clamped to ground by the surge protector box suddenly becomes a 1250 volt pulse on the ground system of the device that is tied to the switching power supply!

That is how network cards, serial I/O and parallel cards and so on, as well as the ground foil lines to the phone jack stuff through external modems gets blasted to bits on computers that are tied both to switching supplies as well as to these common MOV surge suppressed boxes.

Linear power supply devices are not commonly prone to this unique failure mode described above! It's nice to have that $25,000 insurance policy they sell you with each of these wonderful surge jobs. The problem is, that if you really do take a hit, it is almost CERTAIN with one that you WILL have to use the guarantee!

If you use a switching power supply for a ham power supply, you are asking for exactly the same kind of failure mode here. Worse, since you are usually not really well protected from an antenna standpoint, the use of switching power supplies for ham gear is a double disaster just waiting to blow your nice ham gear all to hades during even near misses.

I gave up using ordinary computers with switching supplies in ham gear or commercial radio installations a long time ago. I blew up virtually every computer that ever was involved in one during hits prior to that time. Since going to the Integrand Research industrial cases with the nice big old 40 pound pig iron linear supplies and isolation transformers, I have never (knock on wood), ever had a failure in the sites since.....

From: moritz@ipers1.e-technik.uni-stuttgart.de
Message-ID: <4vc6fq$1d3m@info4.rus.uni-stuttgart.de>
Source record: 103173

Hi All,

I am wondering which may be the best way to wire the TX/RX relay
in a SHF transverter. I could wire the RX input to the NC contact,
thus saving current on receive or I could wire the TX output to the
NC contact and the RX to the NO contact, thus protecting the output
transistors in case the relay fails to close.

Any preferences? Moritz DL5UH

Gentlemen, and I always use the term loosley as I know how I amc
Compliance with any rule or law is needed in a society of strange
creatures the likes of wich we indeed are.

Seriously, can any of us state without a doubt if non-ionizing radiation is
harmful or not???? Folks in the past thought that driving a car on a
sunday spin or sight seeing trip was safe also. Just look at the record

of peoples killed in auto accidents to shoot that theory down. I know, it isn't the same thing, but no one can tell us yay or nay if radio waves will do permanent damage to your neighbors or not. So why not take that extra precaution and put together a system that has preventative measures in the first place, then later on you may be one of the few amateurs still operating out there. Another thought entered my mind (hmmmmm, musta left my mouth open again and one of those pesky things snuck in) about something called "good engineering practice" when building any piece of gear. You wouldn't leave your high voltage tank circut un-protected so that a member of you family could stick a finger in it now would you. (the question is, does the electricity kill you or is it your reaction to the high voltage that does the deed?)
Just a few thoughts from a former broadcast engineer that went through this 10 years ago. (including having to try to deny access to surrounding public lands adjacent to the 100K FM transmitter site.) Wether we agree or disagree with the rules, remember, the FCC and EPA and local and Federal government make the rules and can shut you down right or wrong if you infringe upon them. Also, by having a national standard we will be better off than if every Tom, Dick and Harry has a differant standard that we have to try to follow. So there is no cowardice in following the rules to protect your own hide from bureucratic invasion into your shack and the removal of your equipment and some of your hard earned cash from your person.

523. 16,384 Mhz Frequency Standards

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-20 00:00:00 UTC
From: Douglas Dwyer <ddwyer@ddwyer.demon.co.uk>
Message-ID: <5FbR+BAS3ZGyEw3I@ddwyer.demon.co.uk>
Source record: 103175

I am an OCXO designer, I have a number of unused oven Controlled Crystal Oscillators (OCXOs) at 16.384MHz these units came on the market very cheaply, o one else knew what they were;I bought the lot.
Units are in al boxes hermetically sealed with pins for PCB mounting, I have an off air standard here and can calibrate ie ship with information on what voltage to set to to give frequency to +-0.1ppm when you connect up.
This ration should be good to 1.0ppm over the next few years.
Dimensions 75X50X30mm
These divide by 2 to the power 14 to give 1 kHz to function as the reference for frequency synthesisers as used in instruments, radio, cellular, TV Transmitters..
Oscillators are stable to 1 part in ten to the nine i.e. 0.001ppm.over a wide temperature band.
Excellent spectral purity, measurement repeats to 0.0001ppm per second.
Will operate over -40+70C
12 V supply 500mA on warm up. 150mA when running@23C
Output 1.5 v Peak to Peak sinewave AC coupled, 50 ohms source resistance.
Built in 8V reference so that fine frequency adjustment can be carried out with external potentiometer.

These units are latest technology incorporating SC cut low ageing crystals ageing rate reduces logarithmically and can be expected to age no more than +2 ppm over the next 5 to 10 years, inital ageing already complete as units are over 1 years old.
Units within +-0.01 ppm after 10 minutes perhaps better.

sold at approx 10% of manufacturers price.
Supplied tested with connection diagram.

1 off price from FP Ltd. $75.
To post 1 or two units Swiftair registered $15 Please make $cheque to Douglas Dwyer

The output capacitance is between the plate and elements in the tube
(screen grid or control grid) which need to be well-grounded, plus
direct plate-to-chassis capacitance, so there's no problem in the
'quality' of the ground.

Whether this center-tap is enough to balance the whole circuit will
depend on the degree of inherent (physical) balance, and on the size of
the stray external capacitances to ground compared with the tube's
output capacitance.

>
>I get the feeling that without a well established ground return, the

>muster in any engineering organization.
>
On the contrary, at VHF it *works* for push-pull quarter-wave lines -
and it usually stops working if you add extra grounding!

The problem is that an extra ground converts one parallel-tuned circuit
into two separate but closely coupled single-ended circuits. Unless
these two circuits are identical (which is the same as saying, unless
the whole thing is balanced) they will have separate resonances and
there will be significant common-mode currents flowing through the
chassis between the two different grounding points. The result is that
the circuit doesn't resonate correctly, and there is a large risk of

instability caused by coupling via the chassis currents.

It is very difficult to establish an exact electrical center-tap on a coil, because the coil is inherently unsymmetrical, so the best advice seems to be "let it float". If you want to force a center-tap in addition to the one provided by the tubes, do it on the tuning capacitor - but make sure that the capacitor itself is well-balanced. A butterfly capacitor works best. Experience at VHF is that a more conventional twin-gang capacitor (two sections in line) needs to be mounted on insulating pillars, with a wide ground strap connected from the exact center of the metal frame. The grounding point must be close to the two tubes and on the centerline between them. The variable capacitor must obviously have a low-capacitance insulated shaft coupler and preferably a non-conducting shaft as well.

You may be able to ground the whole capacitor at lower frequencies. But if you're wrong it could mean a major mechanical rebuild, so...

Also note that everything that's been said about the plate circuit applies even more to the grid. In addition to all the other problems, unbalance in the grid tuned circuit will deliver unequal drive to the two tubes. In push-pull grid circuits there are advantages in floating both the variable capacitor and the inductor, and grounding the circuit through a preset differential capacitor to balance out all the strays (two separate preset trimmers can be used instead).

If we have two tubes A and B in push-pull, then when tube A is conducting, the plate to ground capacitance of tube B plus any ground path inductance (assumed to be > 0) back to the cathode of tube A, presents some *possible* problems with spurious resonances and stray currents going where they are not wanted. I like your idea of the butterfly cap with single-point ground. As an alternate, I would like to see a fixed cap from each plate to a common ground point between the tubes to augment the tube output capacitance. Also the RF choke in the coil or quarter wave line B+ feed is good.

535. Re: Question abt Push-pull RF Amplifier plate tank circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-21 00:00:00 UTC
From: k5am@lascruces.com
Message-ID: <4ve3cq$9qq@news.lascruces.com>
Source record: 103065

I think it's clear that one should not r.f ground BOTH the coil and the tuning condenser. But the question still is, Why r.f. ground either?

My guess is that for older, smaller, lower-power, lower-voltage amplifiers, it was very convenient to ground the rotor of the condenser. So the RFC on the coil was needed. But at the KW level it not so much of an extra chore to mount the condenser on ceramic insulators and to use a ceramic shaft insulator (and a grounding panel bearing for safety).

One advantage of not r.f grounding the condenser is that only the r.f. voltage, not d.c. plus r.f., will appear across the plates. Also, there is less chance of a VHF parasitic circuit set up via the condenser through ground.

The advantage of the RFC on the coil is that there is less chance of any significant r.f. currents through the bypass condenser. The simple feed-thru capacitor suggested earlier would be questionable in regard to voltage rating (incl. r.f. voltage) and r.f. current.

So it seems neither need be grounded, and all the mentioned advantages obtained.

Repeating my earlier comment,

>In my homebrew push-pull 4-400A, 50 mc. amp, neither is at r.f. ground.
>No connection at the rotor. RFC, 6 uH, at the coil. Working fine for
>35 years!

Just a quick note on the latest HT, the Yaesu FT-50R:

It's IM rejection characteristics are aided by the antenna. With sweep gear, the antenna exhibits very narrow resonance, only in the amateur band. On VHF, my "rubber duck" has a VSWR of 1.5 between 144 and 148, while 60+ everywhere else. I might as well be using a wet noodle to listen to the WX on 162.400 MHz.

On UHF, the antenna has a much wider response, centered around 380 MHz! At 430 to 450, the VSWR is around 4... not an efficient antenna.

Cellular radio can be tuned at the image frequency, which is (cell freq) + 90.2 MHz. The sensitivity is degraded by only 10 dB (-110 dBm).

539. Measuring 1/4 Wavelength in Coax

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-21 00:00:00 UTC
From: "Joseph M. Zawodny" <J.M.Zawodny@larc.nasa.gov>
Message-ID: <321B46D4.726D@larc.nasa.gov>
Source record: 103069

Thanks for reading this,

I know I am supposed to know all this, but before I start
cutting coax I need to be certain. I am building a pair of phasing
lines / impedance transformers to stack a pair of 70cm yagis. I
need each line to be 5.25 wavelengths (wl) in 75 Ohm coax so I can
get the correct spacing between yagis and also transform the 50 Ohm
antenna impedance to 100 Ohms at the "T" where they'll attach to
the 50 Ohm feedline. My question is this: What is the best way to
assure that I am getting exactly an odd integer multiple of quarter
wavelengths in my 5.25 wl lines? If the Mfgr's velocity factor (0.78)
is off by 5% it adds up to a 1/4 wl error over 5.25 wl of line so,
I need a way to measure the proper functioning of the 1/4 wl (actually
21/4 wl in my case) transformer. My original thought is to solder a
100 Ohm resistor across one end of the 75 Ohm coax and measure the
SWR at the other end at the frequency of interest (435 MHz). If I was
dealing with just a 1/4 wl length of coax I could just trim it to
resonance at 435MHz, but I do not believe this will work with 5.25 wl
lengths.

Any thoughts, comments, or experiences are welcomed.

73,

>
>Also, there is less chance of a VHF
>parasitic circuit set up via the condenser through ground.

The VHF parasitic circuit is usually mostly internal to the tube in a well designed and laid out PA. The tube's grid structure is the major player. Tubes with long thin grid leads and large open grids (811A, 572B, 3-1000, 3CX1200A and D 7) all have low self-neutralizing frequencies and can be prone to parasitics.

Tubes with small compact grids and short coaxial grid connections (8877, 3CX3000, 4CX1000, 4CX250) are relatively immune to parasitics when grids are properly grounded.

So far as the anode circuit, what happens beyond the tank capacitor has little effect on VHF stability. What we absolutely DO want is the capacitor to be well grounded for VHF, and VERY close to the tube. If that is done, only the connections between the capacitor and the tube remains the major player in anode VHF resonance. Inserting a suppressor at that point will allow us to control VHF path losses.

The resistor used in the suppressor MUST be large compared to the impedance of the VHF path, and small compared to the reactance of the suppression coil. Making the VHF path longer and less predictable by not grounding the capacitor moves things in the wrong direction.

It has been my experience that such data bases become a menace because of the few nasty twerps in internet-land that will use such a database to flood all of our e-mail in-boxes with junk e-mail, some of it merely blatantly commercial, but most of it on the order of chain letters.

Count me out. If my e-mail address makes it into your database, I will demand that you take it out.

Don't get me wrong, I am not angry at you. It is not your fault. I am angry at the junk e-mail generators of the world.

Gee Gary,
Good point but now I have a idea.
Lets SUE mfg's and distributors of our lead based solder.
They should had know for years that the stuff was dangerious
if not held in the prescribed manner. I dont think that they had warning
labels on the packages :-)

Bottom line Gary...
Keep up the GREAT posts and responses
I find your text both entertaining anf very informative !

I use a quarter wavelength power divider built from 1" square
aluminun tubing with a brass center conductor. The dimensions for the
center conductor can be found in the ARRL handbook. (I think it is 2.33
to 1- not positive though) I am using one of these on 2 meters & built
one for 70cm for a friend & have 1.1 to 1 swr through them, you also get
to use 50 ohm coax to the antennas.

Don't know exactly what it is you're looking for,
but at 600 watts RF, I don't think it would have
a "core". If you over-saturated an iron or powdered
iron core, you'd cause no untold amount of TVI.

For 600 watt stuff, like in antenna tuners, baluns, etc,
best just to use air core treifilar windings (refer RSGB
or ARRL Handbooks).

Uncle Brian VK6BQN

If the higher imepedence side of the transformer is around 600 ohms or lower, very good 9:1 transformers can be made using choke balans. Three separate 1:1 choke balans wired in parallel on the low impedence side and in series on the high impedence side on 125 or 250 ferite cores would be one option. As long as the choking impedence of the windings is high enough, there will be no core saturation. CQ and ARRL have books by Sevik (sp?) which describe such transformers.

There are a bunch of them. A summary of some relevent ones can be
found at the end of the NCRP Report No. 86 which is a major part of
the the basis for the standard the FCC has adopted. Dr. John Moulder
at the Medical College of Wisconsin maintains a number of FAQs on
non-ionizing radiation exposure. The FAQs have a large number of
references. Look over in sci.med for the FAQs.

>PCBs, work hazards (a lot of hams are in high tech jobs) etc..
>Statisticly speaking, statistics don't work. They are only as acurate
>as the intent and will of the statistitian.

Statistics can show us correlations. Correlation is not necessarily
causation, but it is sufficient to cause us to take a closer look
for a causative link, and if strong enough, sufficient for us to take
prophylatic measures even if we haven't discovered the exact causative
link. For example, if I drop a 2 kg hammer on your foot from a height
of 1 meter, it may or may not break a bone depending on how it lands,
how dense your bones are, etc. Now if I drop the hammer on your foot
1,000 times, statistics say a bone will likely be broken because it
will strike with an edge on a small bone sooner or later and concentrate
enough force to break it. Or, I can take the hammer and drop it once
on each of 1000 people's feet and get roughly the same correlation.
Some people will have smaller bones, some will have brittle bones
(osteoporosis), some will just be unlucky with the impact angle, etc.

Correlation isn't 1 to 1 with causation, but if it is significantly higher than the number of broken toes I see among a population who isn't at risk of having a hammer dropped on their foot, l'm likely to recomend a prophylactic measure like steel toed safety shoes for people likely to get a hammer dropped on their foot even though I can't predict the outcome of any particular drop.

Now if I substitute a 200 kg safe for the hammer, the correlation is going to be so strong that I believe even you might consider wearing steel toed shoes. (That would be equivalent to an RF exposure significantly larger than 10 mW/cm^2.)

>>The frequencies where (RF heating) exposures are most harmful to humans

>
>Couple? I suppose the good doctor had a flesh-dip meter? (GRIN) Did
>he find that the subjects exhibited lower SWR characteristics when
>loaded up for 30-300 Mhz operation vs. above/below?

Indeed, what is regulated is called SAR. SAR is similar in concept to REM for ionizing radiation. Different frequencies of ionizing radiation from soft X-rays to hard gamma have different effects on the body. While you might get the same number of RADs from a dental X-ray as you'd get from exposure to a cobalt 60 source, the REM (Rad Equivalent Man) exposure you'd get is very different. So it is also with SAR. Different frequencies are absorbed by the human body differently depending on a number of factors, including resonance effects, so in a sense the SWR *is* different when the body is excited at different frequencies.

The SAR for various frequencies is determined by calorimetry. The limit exposure is 4 W/kg of heat in the tissue. Experimenters (using corpses) subject the body to different frequencies of RF at a given surface power flux in mW/cm^2 and measure the energy deposited in the flesh for that power flux at that frequency. The result is the familiar chart seen in the ANSI and NCRP standards. Similar to a RAD to REM conversion chart, this chart shows the relative values of biological absorption for a given frequency and surface power flux.

Looked at in antenna terms, the human body is 1.5 to 2 meters tall, and serves as a resonant structure in that range. And when you look at the exposure chart, the frequency range between 30 and 300 MHz is, unsurprisingly, the one with the lowest permissible power density. Currently, SAR is measured only for whole body exposures, but there is some concern that various subparts of the body (notably the skull) form resonant structures at higher frequencies (such as cellular). By the time you get up into the microwave region, however, gross body structures are too large to be resonant, though there can still be localized hot spots in the body.

>operate on the bands they do and not on 10m and 2m? And you say the
>higher freqs are more subtle with regards to effect and heating? I
>don't think so.

Microwave ovens operate where there is ISM spectrum. There happens
to be an ISM band at 2.4 GHz, and magnetrons for that frequency
happen to be cheap to produce. Another ISM band (900 MHz) couples
more strongly to flesh, and is used in certain large commercial
RF ovens, but the circuits are more expensive to produce for a
given heating value, so consumer microwave ovens operate at 2.4 GHz.

There are other ISM bands too. One is 27 MHz. That is used for
plywood drying (hint: 8 foot sheets). Another is a spot frequency of
13.56 MHz (near 20 meters). An ideal frequency for heating flesh happens
to be near 1.4 GHz, the "waterhole" resonance, because the body is 70%
water, but that isn't an ISM band, so the oven manufacturers couldn't
use it.

>"Since the EPA regs were added, a lot of the guys who run QRO call a
>QSO 'OM-BBQ'"

Well, the EPA didn't set these regulations. The Telecommunications
Act of 1996 mandated the FCC to set these regulations based on the
best scientific evidence available, and that's the NCRP-86 and ANSI-92
standards.

>>The new MPE is 1 mW/cm^2 in the 30-300 MHz region. That gives at least

>proof. Statistics are not proof, they are an indicator.
>You can get one set of stats from the media, and read something
>completely different from the MMWRs from the CDC!

>(Morbidity and Mortality Weekly Reports)

Yes, as noted above, correlation is not necessarily causation. But
as also noted above, it can be compelling reason to take prophylactic
measures. (That's particularly appropo for things like AIDS and HIV.
There is a very strong correlation between the presence of HIV in
the body and the development of AIDS. The exact mechanisms aren't
all known, and various co-factors may need to be present, but taking
prophylactic measures against HIV exposure is still a very prudent step.)
The same is true with low level RF exposures. There's no doubt whatsoever
that high level exposures to RF are harmful, immediately and drastically,
but there is also a strong enough correlation at low levels of exposure
for longer term effects to make it prudent to take prophylactic measures
by setting exposure limits.

>EXAMPLE:
>Like the 'assault weapons' crap. You hear how they are the preferred
>weapons of criminals, and used in the majority of deaths in the
>country. Then you read the Governments OWN statistics, you find out
>that 'assault weapons' contributed to about .8% of total gun violence
>in the US. (Firearm inflicted injury, 1995)

Indeed, but that proves nothing either. There are roughly 200 million
firearms in civilian hands in the US, less than 15,000 are used annually
for violent murder (or suicides). That's only 0.0075% of firearms. Most
of the ones used in crime are stolen.

The so called "assualt" weapons made up 8% of all firearms available
"off the rack" for sale prior to Comrade Clinton's ban. If gun type
choice were random, we'd expect roughly 8% of the weapons used in
violent crime would be "assualt" weapons. As you note, the number is
actually 10 times less than that. Does that mean criminals don't prefer
"assualt" weapons? Maybe, maybe not.

Criminals don't choose their weapons "off the rack" because they've
been forbidden to purchase weapons at retail since 1968. They get them
mainly by theft, and the most common firearm stolen is the Smith and
Wesson Model 10 (because there are millions of them out there in civilian
homes, and on police belts, the majority of police killings are with the
officer's own gun), so unsurprisingly, that's also the most common firearm
used in violent crime. But does that make it the weapon of *choice*?

Probably not. Given a *choice* criminals might prefer a submachinegun,
but they don't really have that choice because there are less than
150,000 of them in civilian hands, and they are generally well protected
against theft. So criminals have to settle for less than their preferred
choice and use what they can most easily get.

I happen to believe that criminals wouldn't make an "assault" weapon
their first choice anyway. They're no better than any other cosmetically
challenged semiauto rifle, and they are much harder to conceal than a pistol.
Since criminals generally have to be stealthy, big ungainly weapons aren't

very suitable. But the statistics don't prove that one way or the other.

>Oh no! An excuse to get rid of CW? (GAG)

Actually, the evidence is pretty darn compelling. This is one of the
strongest associations between athermal RF and biological activity.
The range of 5-10 pps is also the range of brainwave activity, and
includes the 7.62 Hz resonance shown to have behavioral effects
in animals.

>>In particular, pulse rates in the 5-10 pps range have been shown

>probably all look exactly alike. I wonder what measurements are made
>with respect to the amount of 'natural radioation' we receive on a
>daily basis? The effects of cosmic rays on human development?

Natural RF radiation exposure is truly minute. There is less than
300 kW-hr daily of naturally generated RF energy on a global basis.
(Mostly due to tropical lightning discharges.) Humans didn't evolve
in a high RF environment. It is only in the last 80 years that
humans have been exposed to any great extent to RF, electric, and
magnetic fields oscillating at ELF to SHF frequencies. That's not
nearly long enough to make an evolutionary adaptation.

Note, there was an error in the H field calc. See the follow up
for a correction. Realize too that this is merely a crude approximation
based on an isotropic source. You have to adjust it for the parameters
of your actual antenna. It can serve as a ballpark estimate, but no
more.

>
>Leonard...

The "hole" fills in every year as the polar vortex breaks
up and the stagnant air is diluted by fresh air from the mid
latitudes. This isn't new, or news. Certain conditions have to
exist for the ozone hole to form. The stratospheric temperature
has to drop below -60 C, the air mass must be stagnant, and
enough Cl or Br radicals have to be present to catalyze the
decomposition of ozone. That also happens once a year.

What has the "whackos" in a tizzy is that in the 1950s there
was no ozone hole that formed once each year, now there is.
As stratospheric Cl and Br radical concentrations have increased,
thanks mostly to CFC discharges, so has the size and duration of
the ozone hole.

Some of us may be tempted to say "so what" to this. The hole is confined to Antarctica and we don't live there (nor does anything else of much global importance). Some of the "whackos" (of the no sparrow, or spotted owl, shall fall variety) are agitated and alarmed. Perhaps we should ignore them. But there are also "whackos" of the "if this goes on" variety who we can't dismiss so lightly.

The global ozone level over the mid latitudes is thinning too. Because conditions aren't as extreme as in the polar vortex, there is no hole (and probably can't be a true hole) at the mid latitudes, but there is a measurable increase in shortwave UV getting through. *We* live in the mid latitudes. This should concern us, at least a bit.

On the flip side, low level ozone concentrations over our cities are increasing. This shields us from the UV leakage through the thinning upper atmosphere ozone layer. But the "whackos" want to *deplete* this ozone layer. They say it is bad for us to breathe. They're right too.

Perhaps there has been over-reaction (led by the "no spotted owl shall fall" crowd), but *some* reaction is prudent. Neither we nor the plants we depend upon have evolved to tolerate the higher levels of shortwave UV now getting through. A cautious step back from casual releases of Cl and Br radicals is warranted.

The dwell time for these radicals is on the order of 50 years, so there's no immediate way of knowing whether serious or trivial harm is being done until it is far too late to reverse the process. So it is wise to take prophylactic steps now in case the effects of increased UV in the mid latitudes causes large scale harmful effects.

You can buy a broadband scanner like the AOR 8000 or Yupiteru MTV7100.
They cover the range from 500 khz to 1650 Mhz or higher, with no gaps
(European models). I use my Yupiteru to listen to TV-broadcasting on
holidays.

An interesting discussion!

When I first heard of the Milham (?) study, I was told that the figures for hams were based on selecting names that appeared in "Silent Keys" in QST and that the "general public" is what the smaller group was compared with. A question I had at the time that has not been answered is if a similarly sized subgroup was selected based on some other criteria was examined to see if the same kind of statistical variations would appear. Apparently, while hams appeared to be slightly more likely to die of some kinds of cancer, they were also slightly less likely to die from other cancers.

It is my understanding that the database on which the study was based is not publicly available. If this is so, the study is seriously flawed in that there is no way I or most anyone else can tell if the conclusions extracted are in fact supported by the data. Given that the observations on which the conclusions were based are unavailable, the conclusions can have no scientific validity. Note that I am not saying that the conclusions are wrong. I am saying that niether I nor anyone I know is able to repeat the observations and independently confirm or refute the conclusions.

Put simply (and crudely), Joe McCarthy had a list of "bodies" too.
How many of HIS claims were true?

Hi,
A few months ago, one either ham-homebrew or qrp-l digests, a company advertised selling a kit for a SIgnal Generator covering 1 - 250 Mhz frequency range. It was a DDS based product. This is not the unit being sold by S&S Engineering, 1 -16 Mhz, DVFO.

Can some one pass me the info for the 1-250 mhz generator, including email and URL if any?

I woould like to hear from someone who is using the S&S DVFO product, any comments about ease of assemblying the SMT parts and frequency stability and warm up time are important to me.

Thanks, W6MIK

Gary,

Once again an eloquent response to a bunch of "WE MUST SAVE CW"
mytho-garbage.

Point of the matter is that a diminishingly small minority of the
amateur community are the ONLY identifiable group of users world-wide
who persist in WANTING to use CW.

Everyone else wants to embrace new techmology and the benefits that come
with it ... we have a sub-culture of nostalgists wants to mandate
horse-and-buggy technology and force it down the throats of the
unwilling.

Well said, Gary ... the concept of BANNING CW is foreign to MOST of us
who feel that it should have been dropped asa REQUIREMENT *long* ago.

I support the use of CW by those who like it and want to use it ...
although I think the CW subbands are disproportionately large.

I just hope that the amateur community will wake up to the realities of
the present and future and abandon the requirement before it's too late.
We need to bring in hordes of creative, computer-literate young folks
who can contribute to the future of amateur networking and restore the
concept that hams are technical leaders and innovators ... before we
lose the bulk of our bands to commercial interests who will put the
spectrum to much more efficient use.

Amateur "technology" is, for the most part, AT LEAST 2 or 3 generations behind current and near-term commercial systems ... not the small groups of innovators that we do have ... I mean the "mainstream" of appliance operators who pound CW, ragchew on 20m or 75m, or are content to check the local BBS or packetcluster on 2m with 1200 baud AFSK ... God!!!, 1200 baud AFSK is ANCIENT!!! ... USER links should be running 64kbps MINIMUM, "network" links even faster.

>right direction?

Ok, you have a 13.8 volt source, the battery has charged to a terminal
voltage of 13.6 volts, how much current flows through your 12 ohm
resistor?

Answer, 16 mA, and power dissipation is 3.2 mW. What's wrong with this
picture?

You can't get a constant current charge to a battery whose terminal
voltage rises as it is charged using just a simple resistor. And you can
never get a battery with a 13.8 volt terminal voltage at full charge
to full charge if you only use a 13.8 volt source. As charging time
tends toward infinity, battery terminal voltage tends toward 13.8 volts,
charging current tends toward zero, and *at* infinite time you'd reach
full charge *except* you haven't accounted for internal battery losses.
In other words, you can't get there from here.

You need a charging source voltage of around 14.2-14.5 volts to
fully charge a 13.8 volt lead acid battery. Fortunately, lead acid
batteries *don't* require a constant current charger (NiCads do).
Lead acid batteries are charged with a *constant voltage* charger.

A fully depleted lead acid battery will *self-limit* the current
it will accept, and doesn't require a current limiter circuit in
the charger. However, you should *never* allow a lead acid battery
to become fully depleted. That will cause the plates to sulfate and
drastically shorten the battery's life. You must quit discharging
a "12 volt" lead acid battery when the terminal voltage reaches
10.2 volts. At that point, 80% of the battery's capacity is
exhausted.

A lead acid battery in that state *can* accept too rapid a charge,
so charging needs to be limited to a safe value. An electronic
current limiter can be used, or a saturable reactor can be used

(a wall wart can sometimes serve as a saturable reactor). But a simple resistor can be used too at the cost of a long taper to final charge.

Lets assume you have a 14.5 volt source, the battery is at 10.2 volts, and you want to limit current to 1.4 A. A 3.7 ohm series resistor with a power rating of 10 watts will handle this chore. As the terminal voltage of the battery rises, charge current will quickly taper to a much lower value (dropping to 216 mA at final taper). When battery terminal voltage reaches 13.8 volts, it will be fully charged. This should take about 4 hours.

Remember, a watched battery never boils. Don't go off and leave the battery unattended for a long period while charging. Or if you must, have a voltage monitor which will shut off the charger when the battery terminal voltage reaches 13.8 volts.

The latter method is better, and protects the receiver somewhat
from static buildup on the antenna or lightning surge. However,
beware, the capacitance between the NC and NO contacts may be
sufficient to couple enough Tx power into the Rx to damage it
at moderate to high power levels. You need to use two relays
and a sequencer to prevent that.

My layperson's understanding of this is that even if we were to be required to file such documents under NEPA (or CEQA in California), they very strongly frown on duplicative efforts. In many cases, existing studies of essentially the same problem can often be included by reference. So, for example, if W1AW were required to do an EIR and the ARRL was sufficiently dilligent in preparing its report, then those of us whose situations were sufficiently similar (or obviously less severe) could utilize their work, and would likely require very minor individual effort. (Of course, this should be considered as the speculation of an untrained concerned citizen and appropriate counsel should be sought if the question at hand applies to you in more than a theoretical or rhetorical context).

Source record: 103099

I don't get it. The HF bands are not useful for high speed digital work. Anyone desiring to experiment with high speed digital modes can get into ham radio and have a blast, without ever having to learn morse: the code ticket was designed for this purpose.

As far as I am concerned, I use CW because it is fun. If we remove the requirment to learn CW in order to be a radio amateur operator on HF, we effectively deny future generations of amateurs the opportunity to communicate with foreign hams who cannot afford the elaborate rigs that americans take for granted, and can only communicate with inexpensive, easily constructed CW HF rigs.

Of course, hams could learn CW even if it was not a licensing requriment. But you hit the nail on the head when you spoke of the "CW Subbands" in a yearning way. Many hams want to eliminate those subbands so they can move their phone contacts there.

SSB is just as outmoded as a means of communication as FM and CW, if you only consider the amount of data you are able to pass in the shortest period of time.

Everything stays in perspective as long as we keep in mind Amateur Radio is a hobby, not a vocation. We do it for fun, not necessarily throughput. Testing should encompass ham radio from A to Z, from amplifier to zero-bias. CW falls somewhere in there between A and Z.

Even as a pre-teen, it was obvious to me that this would be a very bad idea. If i needed that kind of 'third hand', i had solder in a plastic tube which avoided direct contact. 30+ years later, i've looked around for the same thing, but so far, everyone prints on the *outside* of the tube, and i would rather find something else to hold the parts than to ingest even minute quantities of some unknown ink.

> higher than its rated charging current add a fuse or circuit breaker
> between the battery and the charging source.

But if the device supplying the power is an automotive battery with a
voltage regulator of unknown quality, I don't think I want to subject
my 7AH gel-cell to a direct connection as, suppose it is 80% depleted,
Gary Coffman remarks:

> A lead acid battery in that state *can* accept too rapid a charge,
> so charging needs to be limited to a safe value. An electronic
> current limiter can be used, or a saturable reactor can be used
> (a wall wart can sometimes serve as a saturable reactor). But a
> simple resistor can be used too at the cost of a long taper to
> final charge.

So, even if there's a protective diode (to prevent the battery from
running the car, as well as limiting the charging voltage), the charging
rate will probably unacceptable to me, since an automotive charger is
designed to rapidly recharge a battery designed for short, high current
usage (e.g. starting the car) and perhaps off by an order of magnitude.

Now, i don't really care if the gel-cell isn't brought up to full
charge,
but rather i would like it to be usable until i can get home,
particularly
while traveling. Is there a simple circuit that will accomplish it,
with
or without active components?

The smoke from rosin flux is not such good stuff (think about what is in it), so don't inhale too much if you can avoid it. However, worse yet is not wearing safety glasses while soldering- the pop of a bit of flux on the board into your eye is NOT a fun thing- lemme tell U! Nobody is immune- some just think they are. It's like wearing safety belts... U only may need them once in your life, but you'll be glad U had `em when you DO need `em.

Source record: 103104

For that kind of gain/power, there are several good devices. One
that I would suggest would be either the MRF

the MRF557 or the MRF559. Both of these devices work very well at 70cm
and have good gain, and should easily handle the power. One of these
two devices (the '557 I *think* - my Motorola book isn't handy at the
moment...) can actually handle a watt or so. Of course, one needs
to bias it properly and wrap some simple tuned circuits around it (just
some appropriate bits of wire and a bunch of ceramic trimmers - adjust until
it works well...) but that's pretty easy. The 13+db of gain you want may
be a bit much for just one stage, but something like a MAV11 MMIC could
cleanly take it up to 20-40mW cleanly (assuming that you attenuate the 10mW
drive a bit...) Another device that may work is the BFR96. 2
250mW is pushing a BFR96 a bit hard, but that that frequency it should do
OK, assuming that it is heat-sinked reasonably well. The nice thing about
a BFR96 is that they are cheap and likely to be easily available.

>
> 73, Moritz DL5UH

I've been looking around for a 10 meter receiver or transciever project and have been drawing blanks so far. The W1AW receiver in a QST of a year or two ago is intended for 80, 40, or 20 meters, and is crystal controlled. There's an earlier version of that simple direct conversion receiever a number of years back that use the NE602 with an L-C VCO and different amplification. There is also another project in the 1993 ARRL Handbook which uses the MC3362, bypassing the limiter/FM detector, which they indicated was good to 15 meters. (That chip goes to 2 meters normally and i think even 440 with an external VFO). My employment situation right now dictates trading off time for money and i don't currently have scope access. So i'm reluctant to do an R2 or miniR2 receiver and to try to figure out a 10 meter VFO, since the Handbook indicates that's hard to do above about 15 MHz without going to a frequency synthesizer. At the moment, what i'm interested most in receiving is the RS-10/11 downlinks, as that might give me some solid motivation to either teach myself or my computer to copy CW reliably. (It's an open question which is easier...) So, unless some local wants to elmer me, it'll have to be something that i can get working without sophisticated test equipment.

So the next obvious question is how hard is it to modify something cheap, like a Radio Shack CB unit, at least to receive 10 Meters. Is it feasible, for example, to have an external VFO built out of a PPL synthesizer like the MC14515x, which i set frequencies from my computer? (A simple computer interface seems much easier to me than an ordinary QRP rig.) Is there some other approach which might be much better?

Emtech has a new QRP transceiver kit available for only $75, which my ham supply company just started to carry. You can order either the 80, 40,30, or 20 meter version. It is a superhet single signal receiver, with a variable crystal filter (available as an option for $25). The transmiter will put out 4-5 watts max, and adjustable down to the MW range. The keying and muting is very smooth and features solid state antenna switching. The rig also comes with full QSK keying. You supply the cabinet, power plug,and knobs. The rig is guranteed to work as it is put together and tested in steps, you should not have any surprises. Full e-mail and phone tech support is available if needed.

I haven't even put this item in my products data base yet. Thought I would share it's capabilities with the group here first. If interested send me an e-mail and I'll provided more details. Best of 73's Ray

Jim,
Yes I have seen the wabbits at the local Wal-mart store a couple of years ago...
Radio shack was selling a video externder also but not quite sure of the exact frequency tho..
The rabbit and rs's device were am :-(
I have been playing around with some hst 900 mhz fm transmitters that work well but
I just purchased a wave??? 2.4 ghz fm tv extenders that work great
they have patch directional antennas.. even tho the output power was / is stated to be 1 MW we were able to get a p5 picture 1/2 mile away from bridge to bridge.. we will try futher distances and then mount the things infront of 2ft dishes to play with :-)
the cost is a little bit higher at about 160.00 tho

Keep an eye out for those rabbits ;-)

Good luck

Try the following site. They are selling some good Polaroid units centred
around 50 kHz for about 16 dollars a piece and some other stuff. Of course
you will find cheaper units but they are different. These are more directional
compared to smaller units, and more sensitive. Any way check out the specs.

http://cec.wustl.edu/~blw2/index.html

600 Series Instrument Grade Electrostatic Transducer:

The Assembly Comes Complete with Protective Cover
Minimum Transmitting Sensitivity @ 50 kHz: 110 dB
Minimum Receiving Sensitivity @ 50 kHz: -42 dB
Suggested DC Bias Voltage: 150 V
Suggested DC Driving Voltage (peak): 150 V
Operating Conditions:
Temperature: -20 to 160 deg F
Relative Humidity: 5%-95%

I've been teaching myself impedence matching via Smith chart recently, and it's going reasonably well. I noticed that ARRL sells a software package that emulates the Smith chart, and I'm curious to hear of what other people think of it. Specifically I want to design simple power amps in the 5-30 watt range using transistors like Motorola's that are fully characterized for series input and output impedence. In other words, I don't have to guess; I have the complex numbers from the data sheets and just need to calculate the conjugates to create a good match on both sides.

Is MicroSmith useful for this sort of thing? Or is paper just as good?

Do let us know.

Hello everyone. I'm looking for SIMPLE receiver plans. Ideally I would like it to be able to be made from Radio Shack parts, be cheap to make, receive somewhere in the HF bands and to be able to be sensitive enough to receive SSB and CW. Thanks...
Andy

594. Data Book for Homebrewers special ends soon

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-23 00:00:00 UTC
From: qrpbook@aol.com
Message-ID: <4vla5o$b33@newsbf02.news.aol.com>
Source record: 102991

The introductory price on the Electronic Data Book for Homebrewers and QRPers including QRP Yellow Pages expires August 31. The price September 1 will be $23 postpaid U.S.A.

The Data Book by Paul Harden, NA5N, includes the popular series from the Colorado QRP Club newsletter, The Low Down, as well as data pages on discrete and specific electronic components. It also includes lab test results on several popular QRP rigs and QRP sources and club listings. The book has 180 pages and is spiral bound.

There is no other book like the Electronic Data Book for Homebrewers and QRPers. A 'must' for the QRPer, homebrewer, electronics hobbyist and technician.

The book was introduced at the Dayton Hamvention this year and is available from Five Watt Press, 740 Galena Street, Aurora, CO 80010-3922. Fax: 1-800-344-0740. Credit cards accepted. Order form available by e-mail at QRPBOOK@aol.com.

The books are also available from G-QRP Club (U.K.) and CW Ops QRP Club (Australia) and from several ham radio outlets in the U.S.

The introductory price through August 31, 1996 is $17.50 postpaid U.S. and $19.50 postpaid outside U.S.A. Colorado residents add sales tax.

Great book! Very useful. I would buy a 2nd edition. - KOWTS (MO)

Super!!!!!!!!!!!!!!!!! - W3HMS (PA)

This book is so valuable that everyone should have two copies - one safe on your bookshelf and the other to be lost, buried under all the solder, wire and parts of your workbench. - VO1DRB (Newfoundland)

I've already used the book as a reference in my most recent QRP build. - KG5N (CO)

You got me into big doo doo at work! The books arrived and I spent the better part of the morning reading. To heck with the patients! Good work. - WA2YMW

595. Help:Recoton Tweak

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-23 00:00:00 UTC
From: Stephen Puskar <spuskar@concentric.net>
Message-ID: <01bb9119$e215a5a0$2c65adce@crc3.concentric.net>
Source record: 102992

I live far out in the "sticks" with no neighbors for acres. I purchased a Recoton wireless headphone system to listen to DMX while I mow my hours of lawn. The system claims at least 150 range but doesn't seem to deliver that. Are there any tweaks possible to boost the signal a couple of 100 feet so I can listen without experiencing drop-offs or fades?
Thanks
spuskar@concentric.net

596. NTSC >> PAL Converter kits/projects????

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-23 00:00:00 UTC

Hello,

I watch PANAMSAT-2 satelitte here in Australia, basically CNNi.

One problem is that it is received in the American NTSC format of
video transmission and here in Australia we use PAL.

I know that NTSC to PAL converters are available as a ready to use
item but would be interested in building one.

Does anyone know of kits or projects (cct's) for such a project?

Thanks for any help you can offer.

Gary-

I believe you! Now, how does that relate to the average Ham? Although 10 mW/cm^2 sounds like a miniscule amount, it doesn't sound so bad when you convert it to 100 W/M^2 (did I do that right?).

What are "real world" exposure levels that a Ham is likely to encounter in each of several areas of the Ham spectrum? Suppose I have a 100 Watt HF transceiver to a dipole, about 20 feet off the ground. Is anyone at risk while I'm on the air? What if I run a KW? What if I use a beam that is 50 feet up?

How about a typical Two Meter installation?

What I'm leading up to, is that the FCC might accomplish more, if they were to perform the math (or make the measurements) for common situations, and publish examples where harm might occur.

You're on the right track. If you read the Report&Order, other services
like paging, cellular, etc, received exepmtions for specific scenarios
(like for a given antenna, antenna height, and power below some level).

Why the ARRL went with the silly "prudent avoidance" (whatever that
means)approach is beyond me. What exemption did we wind up with? One,
less than 50 watts (irrespective of freqy, mode, antenna type and height.
This makes no sense. The ARRL "dropped the ball" again.

Message-ID: <321CFB19.78C5@netwit.net.au>
Source record: 103117

I am interested to know if anybody is building or has built reveivers using the ne602 device.

I am particularly interested in the design of rf and oscilator coils for such devices and am interested in any
design specifications any one can submit.

EG preselector coils homebrew if coils home brew socilator coils home brew.

I would like to put together a database of designs that could be shared widely.

Thanks

Malcolm Fairleigh

A Gunn Diode is a diode that is used to emit & detect waves in the
radar freq range... not sure about specs but i know you can get one
from one of those automatic Door companies that make doors for
shopping malls & the like... They might be called gunnplexers when
used in this way...

Kari, one chapter in the excellent series by Norm Dye and the late Helge Granberg in; Electronics World & Wireless World should be of value to you; see if you can look up "Using RF Transistors" (one of a long series, and subsequently published as a book; Radio Frequency Transistors- principles and applications) Aug '94. p 694;, this chapter covers signal splitting and combining using B-B transformers.

73, Drew, VK3XU.

Actually SSB is probably still by quite a margin the MOST efficient means of conveying voice information in terms of required RF bandwidth per Hz of baseband bandwidth. Digital techniques for speech transmission that can readily operate in less than 5kHz bandwidth (2.4kbps LPC, for example) sound like crap. (They're intelligible, but they sound like a robot talking in the bottom of a tin can.) The vocoders that provide good voice quality require quite a bit more transmission bandwidth.

If you don't use CW, then probably you wouldn't have QSOs with the
multitudes of foreign hams who use only CW, and have home made
equipment.

> transmission bandwidth.

You're correct, considering only efficiency. But remember that CW is a
much more efficient means of communication than SSB, in terms of

required RF bandwidth per Hz of baseband bandwidth.

I remember having similiar discussions using the same arguments on both sides, back in the sixties. As a young man working in the development of the integrated circuits for the LEM computer for the Apollo program, I walked away from ham radio as being too backward, outdated and out of touch. Telemetry of the time seemed to put CW in a category with smoke signals and stone knives.

A few years ago, I picked up a shortwave radio at a flea market, and tuned in W1AW code practice. To my amazement, I could still copy it after 30 years. I picked up the general class ticket the next month, and passed the Extra class one month later.

I find that I enjoy the CW most of all. It matters not that it is outmoded, I consider every aspect of ham radio outmoded, including satellite work. It's all old hat (But it's fun to fool with) in light of modern technology.

73,

Jim - AD4VL

You must be traveling in elite circles. The yearly income in most countries is a fraction of what it is in the States. I'm sure the rich folks do have big antenna farms, but your average-income ham in Latin America is probably lucky to put up a dipole and get on CW or maybe SSB.

-Has anyone built the HF Amp kit in Amateur radio trader from KD4YBC?
-I remember hearing someone use one but it has been a while since I have
-talked to someone using it. How do you like it? Which one, the 500W or
-the 1KW. Is it worth the money and do you have any problem with the car
-computer konking out? Anything to be concerned about?
-Mike W7CFL

Be very careful putting a big HF amp in your car. I fried the computer
in my Saturn TWICE with a 500 watt amp on 40 meters. The first time
the dealer replaced it under warranty. The second time I told him that
it was probably my amplifier so I had to pay for it, big bux!
Most of the newer (95+) cars are pretty well protected against
RF but don't try it with any of the older ones.

615. Re: Are vapors from solder harmfull?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-23 00:00:00 UTC
From: David Kao <dtkao>
Message-ID: <4vj1cd$pp8@hpindda.cup.hp.com>
Source record: 103131

I would rather believe that it's hramful. There were poisoning reports from an electroinc assembly line in a factory in Taiwan 20 or maybe 30 years ago. Many assembly line workers got poisoned after working in the plant for about a year. After careful study of the case it was determined that the solder vapor was the cause of the poisoning.

Most of the workers were young women. A few workers died and some had brain damage and could never recover. Most workers had damaged liver. The factory was shutdown and went bankrupt forever later. Now if you look around labs and factory assembly lines you will see very effective ventilation system in place to secure worker's safety.

Hope this convinces you that solder vapor is actually extremely dangerous.

Robert--

Communications Concepts is a good source, though you'd better be at least a little familiar with constructing things before picking up their "parts assortments" and circuit boards. I just built their Motorola AN779L broadband 20W amp and it worked well, but there were some ambiguities in the board layout that I had to check against the schematic. If you can't read a schematic well you might have trouble. They advertise in QST.

RF Parts is another source who sells a booklet on building an HF amp, and just coincidentally sells the parts as well, though to avoid the moronic FCC restrictions on selling HF amp kits they don't make it real obvious what goes with what. I have the booklet but haven't built the amp. Definitely get their catalog, tho. (They also advertise in QST.) Pretty much the sole quantity-1 source for a lot of RF power transistors.

Both of these companies, by the way, have provided me with superb service over the years.

Good luck with it.

It is the National LM 1871/1872. They also have application notes to it.
Spraque used to have an encoder/decoder chip set, the National chips
have circuits in them for the RF parts as well.

[I am posting this for a fellow Ham that has the problem. He does]
[not have access to Usenet but he has e-mail so please respond]
[to his address at the end of this message.]
==========

I have a problem with Yaesu FL-2100-B amplifier. When the
standby-operate switch is in the operate position, but listening,
received signals are greatly attenuated. An S7 sig is reduced to S1 or
2. Transmit operation seems normal. Examination of the TR Relay
reveals it is a sealed unit, preventing any spraying of contacts, if
indeed that is the problem.

I wonder if anyone out there has experienced a similar problem with
with a Yaesu or similar amps using 572B paired finals and similar
circuitry such as Heath SB series.

Also does anyone know where a replacement TR relay could be
obtained. Any help would be greatly appreciated.

snip

>>
>A terribly misdirected group. May be so may not be so. Do you have any
>facts to show that rf is harmless.

It is almost impossible to prove a negative. Please show me a definitive study with a properly established scientific basis that will show that RF is harmful. After all, it is your theory.

This is the same science that stated that bran was wonderful, only to state a few short months later that it was not. The same science that stated that ALAR would kill everyone in the free world, only to state later that the basis was flawed. This is the same science that said the cranberries would cause cancer in huge numbers of people, only to be shown to be false.

Chocolate is SIMILAR to marijuana? The center for science? and disease control is headed by a bunch of people who at best are self serving boobs, concerned only about perpetuating their high paying jobs.

I don't KNOW if RF is harmful or not but virtually everything in the human experience is harmful, or at least potentially harmful. Cars kill thousands every year but we raised the speed limit to 75 knowing that there will be an incremental increase in the highway death toll.

The prez has declared that tobacco (cigarettes) are a nicotine delivery system while VERY recently we de-drugged Nicorette gum. My mother has smoked for over 70 years and is in better shape than most 60 year olds I know. I do not condone smoking but I believe that the benefits to society COULD outweigh the negatives (agreed not likely but every bit as speculative as your hypothesis) BTW, could you name any ... ANY person who has been shown to have died from second hand smoke?? Why has the average lifespan increased in the last 200 years?

Point of speculation.... In 23 years scientists will determine that a pack of cigarettes a day will decrease your chances to contract PMS/Prostate trouble!

Every state (to my knowledge) has some sort of law regulating the sale of cigarettes to minors so enacting new laws is just plain stupid

until we try to enforce the current laws.

Get a clue folks, the government is rapidly taking ALL of yur
Constitutional Rights away. Read the Federalist Papers to understand
that the founding fathers were aware of this possibility and
considered it to be the biggest potential problem the country would
face.

Radio Shack sells a $20 omnidirectional FM antenna, about four
feet square, that would undoubtedly make an impressive difference.
Mounted on a football helmet with a short mast, it would almost
certainly resolve your problem.

>Dave
>

Dave,

I'm not talking about traveling in elite circles ... I can't afford that ... I traveled on a virtual poverty budget by turist standards, living on my sailboat (at anchor, not in marinas), eating on the boat or in the local people's eateries not the turist spots, and being in very close contact with the locals.

I'm talking about normal working people and small business operators ... the local ham club group who meet at the Denny's (yup ... Denny's ... I swear to God ... there's a Denny's in Acapulco, for example) once a month for an eyeball QSO. Same story, local equivalent of Denny's, in other locations throughout Mexico, Nicaragua, Costa Rica, Panama, and Columbia.

I spent 2 years plus in those countries and everywhere I went were repeaters, packet radio BBSs, digipeaters, NETROM nodes, etc.

They have 2m FM in their cars (some dualbanders, some with HF rigs, too), HTs on their hips, and use the same Yaesu, Kenwood, Icom, and TenTec rigs that are typical here. A significant proportion have computers and run packet, AMTOR, etc.

What I am saying is that even in countries that are relatively "poor" by our salary standards, the ham community has very similar equipment (mostly brand-name "rice boxes", not homebrew "peanut whistles") as do we Americans.

Thus, the "you have to work CW to talk to most foreign stations" argument is a myth. It does NOT hold water.

A far more effective "requirement" to promote communication with foreign operators would be to require testing in a foreign language rather than in CW. And don't give me the standard crap that CW is the "universal language" ... Q signals are a bunch of bullshit ... essentially zero bandwidth ... compared to talking to someone in their own language.

I'd sure like to know what was in that solder! Thousands,
perhaps tens of thousands of U.S. technicians have worked in
similar environments for many years, with not so much as an
upset stomach.

Count on the PVC detuning the antenna. It will change the electrical
length of the antenna by a factor determined by its dielectric constant
and the ratio of antenna element diameter (and internal position) to
pipe diameter. Using a flexible conductor inside the pipe could make
this an intractable problem to calculate. Cut and try may be the only
way. OTOH, using a rigid conductor fixed in position inside the pipe
would make the design amenable to calculation (and make it reproducible).

>> The closest you'll come to a full kit is to buy the individual
>> parts baggies from Communications Concepts. Because of the
>> problems with 11 neter amps, the FCC has outlawed selling complete
>> kits of parts (a la Heathkit) for HF amps

Not so. Kits are very much legal, they just reqire type acceptance.

Any person or manufacturer *selling parts with assembly instructions*
allowing customers to build a HF amplifer is required by law to have type
acceptance...even the guy selling solid state mobile amplfier kits that
doesn't.

Ther CCI kits are legal without TA because they are incomplete parts kits
without assembly instructions intended for engineering evaluation. That's
the case you have to make stick with the Feds..

It would be a good idea to inject a signal into the antenna termaninal
and then trace the signal to see where the drop in signal strength is
this would be the quickest way to make sure it is the relay.

There *are no CW subbands* (at least not on HF). Leave the RTTY/data subbands alone! That's where the most rapid HF activity growth is occurring.

The point is that there are very few "average income hams" except in a few industrialized countries where "average income" is a substantial sum. Amateur radio is not an activity in which those on subsistence incomes participate to any great extent. A simple examination of the relative numbers of amateurs in impoverished nations versus the number in wealthier nations should make this abundantly clear. Substantially only those elements of a society with disposable income participate. And that's mainly the well to do in societies where there is little middle ground between direst poverty and the upper class.

If you look at the pictures of foreign stations in QST and CQ, you'll see the same sort of Japanese transceivers found in most US amteurs' stations. It is rare indeed to see a homemade station, and when you do, it usually turns out to be quite elaborate (read expensive). That's because most foreign amateurs, just as most US amateurs, only homebrew because they *want to*, and not because they have to. It usually isn't cheaper to build a quality station than it is to buy one.

Some amateurs in the US and elsewhere *choose* to build and operate cheap CW stations of marginal performance, but in almost every case it *is* a choice, and not done by necessity. Homebrewing is great. It is fun and educational. But it isn't a viable route for those in dire poverty to enter amateur radio, even if they had the leisure time to do so (which they almost certainly do not).

Gary

>
>Thanks for any help you can offer.

This used to be incredibly hard and incredibly expensive. Now it is merely hard and expensive. You're far better off attempting to modify a PAL TV set to accept NTSC than you are to build a standards converter.

Lets see what's involved. First you need to matrix decode the incoming NTSC video down to component RGB. Then using flash A/D converters slaved to a 14.318 MHz sample clock which is locked to 4x incoming color burst, you write those component samples into three frame store memories, interpolate them into secondary PAL frame memories to make the extra scan lines PAL has which NTSC doesn't, then clock them out of the memories to D/A converters slaved to a PAL sync generator, and finally feed them to a PAL matrix encoder to produce composite PAL video.

Since the frame rates of the two TV standards are different, you have to "slip" frames from time to time to keep from overflowing/underflowing the frame memories. Fortunately this is easier going from NTSC to PAL than it is going the other way (you have to repeat frames going the other way and so need a *third* set of frame store memories).

You need fast flash A/D and D/A converters, gobs of fast dual port memory, a fast interpolator, and several digital PLLs to keep everything in sync. Parts cost alone dwarfs the cost of a NTSC receiver. It's a lot easier to tweak the sync circuits in a monitor, modify the color matrix decoder, and retune the sound IF so that a PAL set can receive NTSC than it is to do a standards converter. Oh, perhaps you could do a nasty one on the cheap, but the picture quality would be worse than just using NTSC equipment.

>mW/cm^2 sounds like a miniscule amount, it doesn't sound so bad when you
>convert it to 100 W/M^2 (did I do that right?).

That's right, and it's the field you'd see 36.1 cm from the radiation
center of a dipole with a 100 watt transmitter driving it, or 8.1 cm
from a 5 watt transmitter's antenna, IE a HT with a rubber duck held
in front of your face.

>What are "real world" exposure levels that a Ham is likely to encounter in
>each of several areas of the Ham spectrum? Suppose I have a 100 Watt HF
>transceiver to a dipole, about 20 feet off the ground. Is anyone at risk
>while I'm on the air? What if I run a KW? What if I use a beam that is
>50 feet up?

The HF transceiver and dipole would be generating a field in excess of
the standard for H-field exposure (depending on antenna orientation with
respect to the point of measurement). You're still in the near field at HF
frequencies, and the behavior there is more complex. We have to look at
E-field and H-field exposures separately, and not just at power density.
(You'd be Ok with respect to power density alone at that separation.)

A kW would aggrevate the situation. 10 db power gain equates to a 3.16
times larger exposure radius for the same field intensity. A beam on a
50 foot tower would generally be in compliance with the standard, even
at a kW (barring some obscure pattern anomaly caused by the particular
installation, IE feeder radiation). That's because its pattern isn't
isotropic, and the main lobe would be well above populated areas.

>How about a typical Two Meter installation?

An on-glass antenna installation with a 100 watt transmitter in a car
would exceed 10 mW/cm^2 exposure at the driver's (or passenger's)
position. A cowl mount might too. A roof mount would generally be Ok

(except for people standing next to the car). At home, a spacing of 1.61 meters from the operator would be outside 10 mW/cm^2, but would have to be 5.1 meters away to meet the 1 mW/cm^2 exposure standard. In general, the new standard requires a spacing of 3.16 times greater than the old ANSI-82 10 mW/cm^2 standard required on 2m. If you're using a gain antenna, things become more complicated. In the main lobe, safe exposure distances have to increase in proportion to the power gain, in the pattern nulls, safe exposure distances are lessened from what they would be with an isotropic source.

>What I'm leading up to, is that the FCC might accomplish more, if they
>were to perform the math (or make the measurements) for common situations,
>and publish examples where harm might occur.

They did. About a year ago, the FCC OET went out in the field and examined 9 amateur installations picked at random. The results are available as a PDF file on the FCC web site (148 kb file). While many amateur installations were within the NCRP-86 limits, they found some which weren't. And those weren't aberrant installations, but rather some fairly common ways amateurs set up their stations.

IMHO, the most common dangers for amateurs operating VHF+ are on-glass mobile antennas with typical VHF rigs at power levels of 25-45 watts, and using a 5 watt HT held in front of the face. (Note that these setups are exempt from the new regulations for *political* reasons, but that certainly doesn't mean that they are safe. It is no accident that 50 watts was chosen as the cutoff point. Look at the power output of the typical VHF mobile rig, they fall just under the exemption limit.)

For amateurs operating on HF, the big danger areas are indoor antennas and ground mounted verticals. The FCC did find some "hot spots" in stations using open wire feeders or end fed long wires. (Mobile setups are at risk too, but at HF the car body does offer some Faraday shielding for the operator. The big hazard is to members of the public standing outside a parked car that has an operating HF setup.)

A final note. The standard requires exposures to be averaged over a 6 minute period for operators, or a 30 minute period for the general public (whose standard exposure levels are lesser than for operators). So a station whose peak exposures violate the standard may still be Ok if the average exposure level is sufficiently lower than the peak. Again this is a somewhat *political* decision and doesn't mean it is safe.

A non-amateur example: a 250 kW pulse radar whose average power is only 100 watts might meet the standard but still fry your eyes in some situations. Peak power does matter in some cases. I've tried to heat hotdogs by holding them in front of radar dishes with a wooden stick. The dog's surface *explodes* into blisters, but the center remains cold because the *average* power is too

low to cook it through. When I do this using our satellite uplink truck's dish (800 watts FM), the dog cooks nicely because it's in a constant power field of sufficient intensity. Those explosive blisters could still do you harm, even if they don't cook you through like a beam with higher average power can.

> similar to linear amplification?

Yup, it's possible. Airborne VHF communications radios work that way. If you want to try this you need to be aware that the input and output matches for the transistor devices may need modifications. As you will recall, the input and output impedances for a class c amplifier are strongly dependant on the input and output power levels. With collector modulated AM, the power levels are constantly changing.

The inherent non-linear behavior is tough to model correctly and the RF devices don't have good specifications to work in that manner. The best I've seen done is just to diddle with the matches until is works... Any body else?

1/4 of PEP is correct. We use 100 Watt devices to get 25 Watts of carrier power.

Some manufacturers, such as Telefunken, used to make these. I helped a friend (PhD in EE) install one in Italy and it took about 25 man hours.

However, wherever U.S. servicemen are, base exchanges sell multisystem TVs. I still use a multisystem Toshiba (NTSC, PAL & SECAM, + variations, 11 systems in all). Some countries (those which have TV licenses) actually prohibit the sales of these to the general public, but others are more reasonable. Just find out what the model #s are and pester the regular distributor to get one.

It's not homebrew, but the money & time you save will let you do some non-broadcast homebrewing.

Bob Doyle <doyle@primenet.com> shared the following priceless pearls of wisdom:

->The inherent non-linear behavior is tough to model correctly and the RF
->devices don't have good specifications to work in that manner. The best
->I've seen done is just to diddle with the matches until is works... Any
->body else?

Yup. Since aircraft VHF AM radio is where I've spent almost all my engineering career, the best way to do it is to amplify your modulating signal with an op-amp, sniff a little bit of the RF output, rectify it (detect it) and use this as the feedback signal to the op amp. You couldn't care LESS what the modulating signal at the collectors looks like so long as the OUTPUT is a faithful reproduction of the input.

It's still a more viable route than spending a few year's worth of their
family's income to buy a fancy transceiver. I would like to make sure
that the option to cobble together and operate a cheap CW station is open
to lower-income people who want to enjoy ham radio.

Nonsense. We have an off the shelf solution in Clover which gives us 750 bps (in OOK Morse terms that's 1125 WPM) in 500 Hz. We can go faster than that. Using a raised cosine FSM, we can put 38 non-overlapping 50 baud carriers in a 3 kHz channel. That gives 1900 bps while still maintaining a symbol rate compatible with HF multipath. If we use symbol overloading, as Clover does, we can boost that to 4500 bps. If we more aggressively overload symbols and use some simple coding tricks, we can jump to 7600 bps, still in a 3 kHz channel. If we throw in a bit of compression and some FEC, we can do 11.4 kbps. Subtracting overhead, we can achieve a net 9600 bps in a 3 kHz channel without sacrificing our ability to deal with multipath. And we can do that for less than $100 in DSP parts (or even do up through 4500 bps on a PC with just a sound card and a bit of software, IE essentially free).

We aren't limited by cost, there is sufficient bandwidth, but we aren't allowed to exploit it by the regulations, and performance of even the simplest system is so far ahead of OOK Morse as to not even make it a competition (an effective 9600 bps is equivalent to 14,400 WPM using the "PARIS" method of expressing WPM used by OOK Morse adherents, and that's using the full extended ASCII character set (or pure binary data), not just a subset of capital letters and some punctuation). That's more throughput than a whole band full of OOK Morse operators can manage to achieve, and we can do it in a 3 kHz channel. Who's wasting spectrum then?

Under very severe conditions, with large amounts of interference and very weak signals, we can do fallback the same way that Clover or PACTOR II do. Even at the lowest rate, our throughput would still be 47.5 WPM, and that's for a signal you couldn't even hear with your unaided ear. I know this works because I've had Clover contacts with stations I couldn't even detect with my ear, but the modem could. And Clover is not the best method

we could use (it may not even be the best off the shelf, SCS's PACTOR II box is said to be better right now).

Probably not, their choice. If they choose not to use high performance modulations, they miss out on contacts with us. But experience shows that most of the more advanced digital operators *are* non-US operators *now*. Foreign hams seem to adopt technological advances quicker than we do. I know that GRAPES has had more foreign sales of its 56 kb RF modem than domestic sales, and I know I make more foreign contacts on HF digital than I do domestic ones. I believe that says something about the technical astuteness of US amateurs too. We have an off the shelf way to do packet 47 times faster than the typical US amateur does it now, and for about the same total station cost, but US amateurs have not been quick to seize the opportunity to advance. In proportion to their relative numbers, foreign amateurs are accepting the high performance challenge at a rate over 10 times that of US amateurs. If you want to talk about backward amateurs, there's no need to look overseas.

>You're correct, considering only efficiency. But remember that CW is a
>much more efficient means of communication than SSB, in terms of
>required RF bandwidth per Hz of baseband bandwidth.

What's that supposed to mean? A dead carrier would be even more efficient by that metric. "CW" is really double sideband with carrier AM. The only reason it is narrow is that information content is very low. The relevant measure is information per Hertz per second, or in more Morse-centric units, words per minute per Hertz. If we take the ARRL recomended rise/fall time for a Morse element, a Morse signal occupies 250 Hz. Being generous, lets say the average amateur operator can sustain 20 WPM. That gives Morse a score of 0.08 WPM/Hz. By contrast, off the shelf Clover offers a score of 2.25 WPM/Hz. And poor old SSB has a score of 0.06 WPM/Hz (disregarding the nuances of inflection carried in the human voice). So OOK Morse beats SSB (barely), but is totally blown away by Clover. If we look at what we *could* do given proper regulations, we'd have a score of 4.8 for the system I mentioned (and that certainly isn't the last word on what's possible within amateur means today).

>light of modern technology.

Fine. No one is telling you that you can't do that. You can use only old tube type radios too if that's what you want to do, or put any other *self-imposed* limitation on your capabilities that you like. But there certainly are better ways than smoke signals and stone knives. And many of those ways are well within amateur reach, regulations permitting. But the regulations don't permit in several important respects, and that's at least partially because of myths perpetuated about those old smoke signals and stone knives, and resistance to new methods imbued by the current amateur culture of Morse worship as the defining element of amateur radio.

Just look at the current furor over revising the SS regulations. That technology holds promise for large improvements in the way we use and share spectrum, but vested interests with a mindset that narrower is better (the narrowness is really in their own

minds) and that simplicity is a virtue (really they mean simple mindedness, VLSI has rendered arguments against circuit complexity virtually moot) are attempting to shout it down.

This same attitude has been echoed recently on Moon Net. Some EMEers are trying to discourage use of better modulations to displace the need for large amplifiers and huge arrays to do EME. Because those methods would obsolete OOK Morse as the weak signal mode of choice, some are arguing that the newer methods should not be used.

IMHO they're just afraid that their skills will become as obsolete inside amateur radio as they already are outside of amateur radio. So they've decided to try to hold amateur radio as a whole back rather than trying to update their own skill sets, or just accepting that their methods aren't the be all and end all they've been propagandizing for years that they were, and finally accept that they only use them by choice because that's all *they* want out of amateur radio. Now that's fine, *for them*, but it shouldn't be an unnecessary limit on what those who feel otherwise can do.

To those who want to build 2N2222 oscillators and hammer out Morse, I say fine, go for it, if that's what you want. Just don't try to be a roadblock for those who want to build something else, say something using an AD6432 to handle the RF, and a bit of firmware on an AD2181 to do a better modulation coding/decoding, for example, or even for those who want to slip a 20 cent varactor on that 2N2222 and FSK it.

Even Morse addicts are realizing that the receiver's the thing, and that a bit of quadrature and a touch of DSP can be useful in retrieving the modulation of a signal, even the AM of OOK Morse. But receivers work better with a coherent modulation that is tailored to the channel and the demodulating technology available. Hand keyed OOK Morse isn't that modulation, and a pair of headphone covered ears isn't the best decoder anymore either. Like the Boy Scout rubbing two sticks together, the old methods can sometimes still make a fire (especially in the muscles of your shoulders and back), but a magnesium starter is better, quicker, easier to master, and works even when the wood is wet and the wind is howling.

>good?

If you have all the relevant numbers, then a complex calculator
or a Mathcad worksheet are all you need. Where the Smith Chart
shines is in giving you an intuitive feel for what the networks
are doing. In that respect, I think the paper charts are better,
giving you a tangible hands on intuition. But the better Smith
Chart software usually includes a complex calculator, and the
graph on the monitor still gives you an intuitive look at the
network. It'll save you a bit of time, whether that's worth the
price is up to you.

656. HARDLINE CONNECTORS WANTED

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-25 00:00:00 UTC
From: Bruce KD1MW <shiso@ici.net>
Message-ID: <322071A4.4213@ici.net>
Source record: 102950

Hello all: I am looking for "N" type hardline ends -HCC 78-50NM, too fit a length of 1" hardline (flexwell) that I just picked up, used. The cable has lettered on it, Cablewave Systems 16733-810929-00 HCC 78-50 TCC 650 972 FT Flexwell. There is one end on the line now with air valve and guage 0-5 PSI. Please advise, any help is appreciated. Also what gas gets compressed in this line? Thanks, Bruce KD1MW shiso@ici.net

>
>Gary

Gary is right. A modified TV or a multi-standard one is the cheapest
solution, unless of course, you wish to record the NTSC signal on a PAL
video.

Panasonic make a world-wide VHS machine known as the NV-W1. This
machine will play any VHS tape of any standard from anywhere in the
world and output the video signal to any TV standard you wish. It will
also record any TV standard from any other TV standard you care to feed
it with as it has a standards-converter built-in. It will replay, but
not record S-VHS tapes and does not have a built-in tuner.

Here in the UK, its sold for about 1800 pounds sterling.

Maybe, with the aid of a service manual, you could bastardise one of
these ? Hope you're able to work with surface-mount devices. :-)

Good luck,

Ever consider making your own? I like Hline for its' low loss, but
have a limited budget. Given that, I scrounge 1/2 and 7/8 inch 70 ohm
catv cable. If you sweet-talk 'em many cable companies will give you
the (relatively) short ends from a spool. The scrap man was gonna get
'em anyway... I use copper pipe, telescoping hobby shop brass tubing,
hose clamps (split copper/brass to clamp on Hline od), and a dose of
coax seal. Cover the entire mess with Scotch Super 33+ tape (never
use the cheap stuff - bad investment) and have a $5 or so end on the
cable.

REVIEW OF PATENTS RELATING TO SYNTHETIC TELEPATHY

By Judy Wall

RESONANCE

Newsletter of the Bioelectromagnetics Special Interest Group

Judy Wall, Editor, 684 C.R. 535, Sumterville, FL 33585 USA

Sample of Newsletter $4.00, Subscription (4 per year) $15.00.

Number 30, March 1996

Pages 38 to 44.

There are at least two patents dealing with the concept of transmitting sound, voices, and other audio phenomena directly to the brain, bypassing the normal auditory processes commonly associated with the sense of "hearing." In a previous article this situation was called "synthetic telepathy," and literature reviewed at that time revealed only the most rudimentary research had been done to support the existence of this phenomenon. Synopsis: In 1961, Allen Fry documented the ability of the human brain to "hear" certain microwave pulses. Joseph Sharp and Mark Grove, in 1973, successfully performed an experiment in which words were modulated onto a microwave frequency and communicated directly to the human brain. A.W. Guy et al. stated that the most likely mechanism for the interaction of the electromagnetic (EM) field with the brain was by the conversion of the EM energy to acoustic energy through thermal expansion.(1) Mike Coyle updates Frey's research [MC: see Appendix A. for this update] elsewhere in this issue to include the possibility of other mechanisms, including direct interaction with the magnetic fields around neurons.

FLANAGAN PATENT

Dr. Gillis Patrick Flanagan has over 300 inventions to his credit. At the age of 11 he invented his first device, a "sleep machine." At the ripe old age of 14 he invented the Neurophone, a radio transmitter that, when connected to the body through electrodes, sends electrical impulses through the human nervous system directly to the brain. He says, "When I first applied for a patent on the device, no one at the patent office believed such a device could possibly work." As a result, it took six years before he received the first patent, and that was "only after we made a nerve-deaf employee at the patent office 'hear' for the first time in fifteen years."(2)

The patent here described is U.S. #3,393,279, applied for March 13, 1962 and granted July 16, 1968, entitled "Nervous System Excitation Device" and the abstract reads:

"A method of transmitting audio information to the brain of a subject through the nervous system of the subject which method comprises, in combination, the steps of generating a radio frequency signal having a frequency in excess of the highest frequency of the audio information to be transmitted, modulating said radio frequency signal with the audio information to be transmitted, and applying said modulation radio frequency signal to a pair of insulated electrodes and placing both of the said insulated electrodes in physical contact with the skin of said subject, the strength of said radio frequency electromagnetic field being high enough at the skin surface to cause the sensation of hearing the audio information modulated thereon in the brain of said subject and low enough so that said subject experiences no physical discomfort."

Excerpts from the patent read:

"The present invention involves the discovery that certain electromagnetic waves induce responses in the nervous systems of mammals. In human beings a response is produced when some or all of a person's nervous system is placed within a field of electromagnetic waves having a radio frequency above the audible range. In addition, when the nervous system of a person is contacted by modulated electromagnetic carrier waves of such a frequency, the nervous system is responsive to the modulation of the carrier waves. Each individual nervous system is at least somewhat selective in respect to the frequencies to which it is most responsive. ...

"In the method of the present invention, a response is initiated in the nervous system of a mammal by disposing at least a portion of that nervous system within a field of electromagnetic waves of a radio frequency above the aural range. ..In a particularly preferred embodiment of this invention, at least a portion of the nervous system of a person is exposed to audio modulated electromagnetic waves having a radio frequency such that the person experiences the sensation of hearing, substantially free of distortion, the information which is conveyed by the modulation.

"The present invention may be used as a hearing aid, as an aid to teaching speech to a person who was born deaf, as a means of communicating with persons in locations in which the noise level is high, as a device by which a person can listen to an audio signal that cannot be heard by the others, etc."

This last sentence presaged a later application of the Neurophone to save the lives of American soldiers during a Vietnam War. Ordinary communication devices with their high extraneous noise levels, when used in the stillness of tunnels, would give away the soldier's location to the enemy and result in his immediate death. The Neurophone granted our soldiers access to communications while cloaked in acoustic imperceptibility.

This remarkable device can enable people born deaf to "hear" -- some immediately, others with some practice(5), but an amazing accomplishment nonetheless. At the time of invention Flanagan was offered one million dollars by a Corpus Christi company if he could adapt it to send visual images to the brain so that blind people could "see."(3)

The neurophone may be used for subliminal and/or superlearning as it transmits data directly into the brain's long-term memory storage banks, although Dr. Flanagan did not mention exactly when he first became aware of this remarkable property of the invention. He also said that the audio information could be modulated onto a microwave carrier, as in the following Stocklin patent.(5)

The original patent utilized vacuum tubes. Flanagan later applied for a patent on an improved digital version using transistors, U.S. #3,647,970, entitled "Method and System for Simplifying Speech Waveforms," patent applied for August 29, 1969, granted March 7, 1972. The abstract for the patent reads:

"A speech waveform is converted to a constant amplitude square wave in which the transitions between the amplitude extremes are spaced so as to carry the speech information. The system includes a pair of tuned amplifier circuits which act as high-pass filters having 6 decibel per octave slope 0 to 15,000 cycles followed by two stages, each comprised of an amplifier and clipper circuit, for converting the filtered waveform to a square wave. A radio transmitter and receiver having a plurality of separate channels within a conventional single side band transmitter bandwidth and a system for transmitting secure speech information are also disclosed."

Later in the patent we read:

"This invention is concerned with a method and system for simplifying a complex speech waveform so that it can be used for a multitude of applications... The simplified speech waveform can be transmitted directly through the earth or water as a pressure wave, and understood, either directly from the medium, or after simple amplification. The simplified waveform can easily be encoded by scrambling to provide secure voice communications..."

At this point, the Department of Defense slapped a secrecy order on Flanagan's invention and he was not allowed to work on it nor talk about it to anyone for the next five years.(4) He does not know why they did it nor was he compensated for the loss of time or money (as it was not yet in production, the argument went, there is no monetary value to be compensated for). He speculates it might have been for any of several possibilities, the "secure speech" being one.(5) Chuck Allen suggested it was for the "underwater communications possibilities" to contact submarines. An interesting thought occurred to me in comparing

the date of the patent with the date of the Sharp and Grove experiment. Did those scientists for the military get their inspiration from young Flanagan's patent?

Patrick Flanagan states that he does not believe that the Neurophone can be used to accomplish a state of "mind control" as is so often associated with the idea of "artificial" or "synthetic" telepathy. That type of situation requires a person to be in a state of hypnosis or lessened awareness, and disconnectedness between the two halves of one's brain. The Neurophone, on the contrary, effects the synchronization of the brainwaves between the two halves of the brain, into a state of phase efficiency which makes the brain hemispheres coherent, approaching the Zen meditative state, thus facilitating a super awareness and the superlearning ability.(5)

After the secrecy order was lifted, the Neurophone was marketed, but with only about 1,000 being produced. The good news is that this remarkable invention will again be available to the public in about 3 to 6 months' time. Patrick and his wife Gale Crystal are now in the process of setting up production. See the end of the article on how to contact them for more information.

STOCKLIN PATENT

A second quite remarkable patent, of more recent origin and complicated circuitry, by Philip L. Stocklin, is entitled simply "Hearing Device," dated August 22, 1989, and the patent number is U.S. #4,858,612. The abstract reads:

"A method and apparatus for simulation of hearing in mammals by introduction of a plurality of microwaves into the region of the auditory cortex is shown and described. A microphone is used to transform sound signals into electrical signals which are in turn analyzed and processed to provide controls for generating a plurality of microwave signals at different frequencies. The multifrequency microwaves are then applied to the brain in the region of the auditory cortex. By this method sounds are perceived by the mammal which are representative of the original sound received by the microphone."

This patent clearly picks up on the idea of beaming sounds directly to a person's brain by means of a microwave carrier frequency. Following are excerpts from the patent:

"Results of theoretical analysis of the physics of brain tissue and brain/skull cavity, combined with experimentally determined electromagnetic properties of mammalian brain tissue, indicate the physical necessity for the existence of electromagnetic standing waves, called "modes" in the living mammalian brain. The mode characteristics may be determined by two geometric properties of the brain; these are the cephalic

index of the brain (its shape in prolate spherical coordinates) and the semifocal distance of the brain (a measure of its size). It was concluded that estimation of brain cephalic index and semifocal distance using external skull measurements on subjects permits estimation of the subject's characteristic mode frequencies, which in turn will permit a mode by mode treatment of the data to simulate hearing...

"...This invention provides for simulation of microwave radiation which is normally produced by the auditory cortex. ...

"Neural stimulation results in the generation of a broad band of microwave photons by the change in rotational energy state of protons integral to the neuron membrane of the auditory cortex. The physical size and shape of the brain/skull cavity, together with the (semi-conductor) properties (conductivity and dielectric constant) of the brain tissue provide an electromagnetic resonant cavity. Specific single frequencies are constructively reinforced so that a number of standing electromagnetic waves, each at its own single electromagnetic frequency in the microwave frequency region, are generated in the brain. Each such standing electromagnetic wave is called a characteristic mode of the brain/skull cavity. ...

"The auditory cortex in the normally functioning mammalian brain is a source of microwave modes. The auditory cortex generates these modes in accordance with the neural stimulation of the auditory cortex by the cochlear nerve. ...

"In this invention, the function of the ear, the cochlear nerve, and the auditory cortex are simulated. Microwaves simulating the mode matrix are inserted directly into the region of the auditory cortex. By this insertion of simulated microwave modes, the normal operation of the entire natural hearing mechanism is simulated..."

A block diagram is shown of Figures 1 and 2 of the patent (here semi-combined), as well as Figures 8 and 10.

Basically, "A microphone pick-up is amplified and driven through a bank of 24 audio filters to produce 24 audio bands. These are used to amplitude modulate 24 RF milliwatt transmitters. The combined RF signals are transmitted through a suitable antenna into the person with impaired hearing due to damage to the ear, the cochlear nerve, or the auditory cortex." My thanks to Donald Stratton for this simplified version of the patent's operation. It appears to be much more complicated than the Flanagan patent. Those of you interested in the engineering details should obtain a complete copy of the patent for further perusal.

More excerpts from the patent concerning determination of the subject's microwave mode frequencies: The first method is by using a modified microwave hearing generator in which one oscillator signal is beamed at the subject and varied until the maximum perception value is discovered. "The perception, however, may consist of a buzzing or hissing sound rather than a tone because only one microwave frequency is being received. The first test of perception is to determine the subject's lowest modal□ frequency for audition (M=1). Once this modal frequency is obtained, the process is repeated for several higher modal frequencies..."

Another method is given: "Purely anatomical estimation of subject's modal frequencies is performed by first measuring the maximum lateral dimension (breadth) L Figure 8 of the subject's head together with the maximum dimension D (anterior to posterior) in the medial plane of the subject's head. D is the distance along Z axis as shown in Figure 10. The ratio L/D, called in anthropology the cephalic index, is monotonically related to the boundary value _E_o defining the ellipsoidal surface approximating the interface between the brain and the skull in the prolate spheroidal coordinate system. _E_o defines the shape of this interface: _E_o and D together give an estimate of a, the semi-focal distance of the defining ellipsoid. Using _E_o and a, together with known values of the conductivity and dielectric constants of the brain tissue, those wavelengths are found for which the radial component of the electric field satisfies the boundary condition that is zero at _E_o. These wavelengths are the wavelengths associated with the standing waves or modes; the corresponding frequencies are found by dividing the phase velocity of microwaves in brain tissue by each of the wavelengths."

A third method: "A subject's microwave modal frequencies may also be determined by observing the effect of external microwave radiation upon the EEG. The frequency of the M equal 1 mode may then be used as a base point to estimate all other modal frequencies ...the subject is laterally irradiated with a monochromatic microwave field simultaneous with EEG measurement and the microwave frequency altered until a significant change occurs in the EEG, the lowest such frequency causing an EEG change is found. This is identified as the M+1 mode."

Dear Ms. Wall,

[...]

I read "Synthetic Telepathy" with interest as you reference a paper written by Allan H. Frey in _Aerospace Med._, 1961. I possess a copy of a paper he wrote in 1962 for the _Journal of Applied Physiology_ on the same subject titled "Human Auditory System Response to Modulated Electromagnetic Energy." This article seems to be a result of Frey's further work in this area and modifies his earlier statements, made in the 1961 article, about the location and mechanisms of the RF detector in the auditory system.□
In your article it is stated, "This produces an acoustic stress wave that is conducted through the bone to the cochlea.

THIS COPY OF MINDNET #59 BREAKS OFF HERE.

By goom, you're right! I did it the hard way - I noticed Ken Harker had capitalized a V in the middle of one of his sentences. I assumed this was "I" (what other single letter do we capitalize?) and translated (rotated) the alphabet accordingly. Everything fell out nicely from there.

After deciphering "If you can read this, you really ought to get out more," I decided the effort greatly outweighed the rewards!

Good idea...

So we have this feedback suggestion to linearize modulation, and also the question of change in input/output impedances when re-biasing for Class C.

Big question: if you run the MRF454 transistors at about 100 watts carrier, can they take the peaks of current/voltage of 100% modulation? (Of course, all other associated output components would have to handle this also).

If not, maybe one should just be happy with the 30-some watts carrier power of all-linear amplification if only occasional AM is contemplated?

663. Re: Are vapors from solder harmfull?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-25 00:00:00 UTC
From: gradyr@mindspring.com
Message-ID: <gradyr-2508961956120001@news.mindspring.com>
Source record: 102957

As a new HAM operator and one who is studying and has done sampling for lead exposures as well as the constituents in solder, maybe I can shed a little light on the matter. Yes, solder fumes are harmful. The question though is how much dose and how often is the exposure should be your worry. I remind you that oxygen in large enough dosages is toxic also.

Solder may contain several metals. The two that come to mind readily are Lead and Tin.

For specific numbers on the solder you use, request a MSDS from the manufacturer. MSDS stands for Material Safety Data Sheet. The MSDS will tell you exactly what quantities of metals exist in the solder. It will also mention first aid procedures and symptoms related to over exposures.

Lead has a boiling point of 3164 degrees F and the melting point is 621 degrees F BUT the lead you will inhale while soldering is in the solid state. The heat from the soldering will help make the lead particulates rise up possibly into your breathing zone.

Lead is sufficient quantities can reside inside your body. It will affect your Central Nervous System and can cause sterility and birth defects. If you are of child bearing age and you/ or spouse want to have children, the effects of the lead can be serious. This is also true if you are a male. High lead levels can damage your sperm enough to cause birth defects in your unborn child.

To prevent exposures to lead (no exposure is ALWAYS the best exposure):

Set of a small vacuum system and filter the air. Nothing fancy needed. A dustvac with an extension up to your bench works wonders!

If anyone needs any advice,etc on the matter, drop me a line. I'll be glad to help where I can.

Microsmith is fine; I have a copy. However, for what you want to do, Motorola
has a freeware program, "MIP", if I recall the name correctly. It has a
couple of little quirks, but the price is right.

I got a copy direct from Motorola on disk, but I think you probably can find
it online some place.

Was wondering if anyone could point me toward the right direction in obtaining schematics and/or kits for a couple of items.

Since I'm a no-code right now (working on it though!) I'd like to work the 6 meter and some of the MW range.

First off, what about a schematic and/or kit for a 6 meter radio?

And secondly, what about a schematic and/or kit for a RADAR Gun? I am assuming this one is legal of course. Correct me if I'm wrong here! Was wanting to build a RADAR gun and clock vehicles,check speeds,etc.

I'd prefer schematics and parts lists but will take what I can get.

TIA,
Grady

>Zack KH6CP/1

Or to add my two cents. All circuits have resistive and reactive components,
some on purpose and some parasitic. As frequency goes up, the reactance of,

say a stray capacitor, goes down. As a result, intentional resistances must be held low so the parasitic capacitors don't bypass (short) them.

The gain of a stage is, in the case of a simple grounded emitter stage, Rload/Remitter. Even if no emitter resistor is used (highest gain) there is resistance in the material the emitter is made out of. Result - less gain. Sad fact of life - the parasitic resistances don't change or maybe get a little higher with increasing frequency. A fancy way to say this is that a given device has a gain-bandwidth product. The higher the frequency it must pass, the less gain available.

Because we're keeping circuit resistance low to minimize the effect of stray capacitors, we are drawing more current from the power supply than we would at low frequencies. Thermal design limits the power I can put in to a stage and a low gain leads to low power out.

Ok, but why not use more stages to get any gain, and therefore power, we may want. You can, but it's going to cost you. Power is I^2 *R so we have to increase one or both. The transistor has a current limit and parasitic circuit elements dictate a low R - resulting in a maximum power.

Yes there are tricks and there are other technologies, but for reasonable cost, power, weight you quickly have to make the compromise you see the commercial equipment coming to. The good news is that less power is needed at higher frequencies. Don't think of antenna size in feet. Think of it in wavelengths. A given antenna area becomes a lot of wavelengths as frequency goes up resulting in more antenna gain. Less power and more antenna gain results in the same radiated signal strength.

668. 4CX250B as GG TRIODE amp ???

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-25 00:00:00 UTC
From: scottcr@wkuvx1.wku.edu
Message-ID: <1996Aug25.214331@wkuvx1.wku.edu>
Source record: 102962

Q. Can 4CX250Bs be operated grounded grid as a triode for HF ?

I've seen sweep tube amps (tetrodes) with both grids tied, operated as grounded grid triodes, for stability and to get by without a regulated screen supply.

I bought a very nice surplus commercial HF amp without supplies, that covers 2-30 mhz using two 250Bs, (and a driver stage which I removed). The whole thing is made very nicely, and is presently grid-driven and neutralized. If I matched the cathode impedance on the input, driving it with 50-100 watts, it sure would be nice to just supply a grid or cathode bias and plate voltage, omitting the neut circuit too...

I really want to make it work without neut. One alternative would be to use a 2:1 or 3:1 Unun on the input, and swamp it with a 300-400 ohm resistor on the grid side. But... still gotta mess with the screen supply.

Anyone done this?

I think you are stuck re-biasing no matter what you do, if you use class c. My guess is that the amplifier will oscillate without matching changes.

I don't have my "Circle M" books handy... but about the only thing that doesn't have to be rated for 100W is the heat sink.

Believe it or not... most that I know of, do.

Residual FM can be a real issue especially in countries with aggressive adjacent channel power specifications (Germany et. al.). Actually, to me, it is simpler to think of the issue as Phase Modulation, but the result is the same.

You'd think that in this age of high-tech, we'd have moved on by now...

Oops, just to clarify a bit...

The "non-linearity" I was speaking of was the text book "Large Signal"
behavior of the class-c amplifier proper. This issue to be solved is
that the capacitances and other parameters of the amplifier are changing
with the instantaneous collector voltage of the device which is changing
with the modulation waveform. Incorrect matching in this scenario
yields spurrious and/or parametric oscillations!

A standard FM class-c amplifier only has to deal with much narrower
range of collector supply voltages and thus the matching issues with
respect to oscillations are much simpler.

I don't believe that what you suggested would cure any amplifier induced
oscillations. Basic amplifier stability would be a prerequisite.
Correct me if I'm wrong...

What this would cure is any distortion ("non-linearity") between the modulation signal and the generated RF envelope.

Never the less, your idea is valid. I may try it sometime. Many aircraft VHF radios already have forward and reflected power monitors which could be used for this purpose.

It is available at www.fcc.gov. It is longgggg.

This is where I found it after being alerted by the FCC Daily Digest.

Also on the Daily Digest. Recently Centel Cellular was fined $3,000,000.00
for tower violations. Seems that they do not understand Air Safety Zones.
A tower 187 feet high, 2.8 miles from runway, no lights! Did not reply
to FCC for site data. Filed with FAA 5 months after tower operational
for permission to erect tower. What a list of problems. Fine reduced to
$2,000,000.00. After 6 zeros, what does it matter the number in front?

yeah, when they work they're grand. but there seems to be little if any rechecking to see if a url on file at a search location is really there - so you might get 1 of a million possible listings with about 999,000 of them unusuable at all.

of course, there's one location where you have to download files (getting a catalog), expand, run an installation program on the data, then you find you have a bunch of directories and a ton of HTML files to pull up in the browser to view 'em...(now, THAT'S comedy). <sigh>

I've built the CCI power amp kit -- based on Motorola AN779 (push-pull MRF454's). I might want to try a little bit of AM, and I know if you want to amplify AM with a linear you have to keep the PEP at the rated output, thus carrier at about 1/4 the PEP rating of the amp.

Any remote chance one could collector modulate this amp (assuming you re-bias it for Class C? [easy to do])? Would the power ratings end up similar to linear amplification?

Message-ID: <3221B345.6F31@pop3.harborcom.net>
Source record: 102885

I just finished an interesting paper by Ken Dierberger on a class-C ISM designed kw amp that includes a 300VDC PFC supply. The paper was presented at RF EXPO EAST 1995 and describes a push-pull transfomer coupled class-C amp designed to use Advanced Power TechnologY's ARF444 and ARF445 MOSFETs. The amp is designed for 13.56Mhz CW operation and is supposed to be over 80% efficient at full output.

According to the author, its PFC type supply will soon be required on all US RF amps at the 750w and above level and is currently required on all European equipment already. A neat feature of their design is that it directly switches rectified 110VAC to maintain the 300VDC output avoiding any DC-DC stages that other RF device might need for operating voltages. The RF devices for the design are also electrically insulated internally from their cases so they can be directly heat-sink mounted for maximum thermal efficiency (and min $$).

Since it is class-C and ISM rated, several changes would be required by anybody trying to construct communictions equipment around it. I am curious as to whether anybody else has run across this design and if they have any experiences with making the required changes for an HF amateur all-mode amp?

Hello Drew,

Very well said. One might add that some CW ops even purchase
expensive NEW equipment and use it almost exclusively on CW. So it is

not necessarily cost-effectiveness or homebrewing that drives the CW enthusiast. He enjoys CW for the love of it. To do something for the love (pleasure, enjoyment, reward) of it, is, as has been pointed out earlier, the MEANING of the word AMATEUR.
Why is it that so many folks cannot understand why one would prefer to use something considered technologically obsolete? Perhaps they may not be amateurs at heart, doing what they love doing. Perhaps they are merely driven by the mentality of doing what is "new" or "in", or "the latest". Doing this, one puts oneself on an endless treadmill, at the mercy of marketing hype, constantly "upgrading" to the "latest", the "newest", etc etc ad nauseum. I have run into this when working AMTOR and PACTOR in recent years. Many whom I talk with on these modes have 'upgraded' rigs, computers, controllers, software, endlessly in search of the the newest and best. Many do not even know why one mode may or may not be "better" than an older one. They just buy it to have the "latest". Pity them. They are never satisfied, and never really understand what they are buying or why. They are mindless purchasers, the consumer mentality, who apparently never get buyer's remorse. They are a marketer's dream.
Far better to be a participant in something not new, maybe old-hat, and have a real love for it, cameraderie with fellow enthusiasts who communicate with it every day, have knowledge of what it can and cannot do, and possess the skill for expert usage. For myself, I have found nothing to equal it in my 41 continuous years of ham radio operating. Fortunately, I am not alone.

73,
Don, W6JL

The I-V curve of a tunnel diode _does_ have a region where the slope is
negative. In this region, V/I is positive, so technically the resistance is
positive, but the incremental resistance (sometimes called "dynamic
resistance") is negative due to the negative slope. I don't know about Gunn
diodes.

NO ES CASINO. GANE DINERO DESDE AQU�, EN INTERNET.

Hola !!!. Si alguna vez te preguntaste "C�mo puedo ganar una cantidad
de dinero importante en muy poco tiempo ? ? ?", o si ten�s deudas
que deseas cancelar,tengo algo que te puede interesar. Sentate c�modo,
relajate, y preparate para escuchar esta interesante propuesta ! ! !

Quiero comenzar diciendo que YO LO LOGRE ! . Realmente lo encontr�.
Yo particularmente no me conformo con ciertos esquemas de marketing
de productos, o con cadenas, o con listas de la amistad, o con
.... la lista ser�a bastante larga. Desde muy joven particip� en todo
tipo de "negocios rentables" de los que no logr� lo que realmente
quer�a,
y como resultado de eso, gast� $35 por aqu�, $64 por alla, y $105
mas all�. ESTABA EQUIVOCADO ! !.

Hace algunos meses, navegando por un NEWSGROUP, v� un art�culo que
dec�a COMO OBTENER CASH RAPIDO ! !. Lo primero que pens� ... "Aqu� , en
Internet ??, bueno, todo es cuesti�n de informarme para luego sacar mis
conclusiones". El art�culo describ�a la manera de ENVIAR POR
CORRESPONDENCIA UN BILLETE DE 1 DOLAR A CINCO PERSONAS, Y GANAR
$50.000.-
EN EFECTIVO EN 4 SEMANAS !!!. Cuanto mas pensaba en esto, mas aumentaba
mi curiosidad. Por qu� ?. Por la manera en que esto funcionaba Y PORQUE
MI INVERSION SOLO SERIA DE 5 DOLARES. ESO ES TODO LO QUE YO PAGUE !!!.

Est� bien, en ese momento $50.000- me parec�a demasiado dinero para
este sistema, pero era posible. Sab�a que de todas maneras podr�a
obtener $1.000 o $2.000.-. Entonces lo hice !!!. Segu� las
instrucciones del art�culo, mand� un billete de 1 d�lar a cada una de
las 5 personas que aparec�an en la lista. Inclu� una peque�a nota con
el d�lar que dec�a :"Please Add Me To Your List". Luego borr� el
primero de los nombres de la lista de cinco, desplac� los otros cuatro
una posici�n mas arriba, y coloqu� mi nombre en la posici�n 5 de la
lista. De esta manera es como el dinero comienza a entrar !!!.
Luego envi� el art�culo (ya modificado con mi nombre) a TODOS LOS
NEWSGROUPS, BOLETINES LOCALES Y BBS QUE CONOCIA. Luego me qued� viendo
como llegaban los billetes. Yo esperaba recibir $1000 o $1500, pero todo
esto se volvi� muy excitante al ver que las cartas llegaban !!!. Recib�
cartas de paises de todo el mundo. No recib� ni $1000 ni $5000..
Recib� un total de $22.422.- !!!. No pod�a creerlo !!!.

Tengamos en cuenta que NO HAY CIENTOS, NI HAY MILES, HAY
CIENTOS DE MILES DE NUEVOS USUARIOS DE INTERNET TODOS LOS
MESES ! ! ! ! !

En estos momentos no solo dispongo de dinero para seguir pagando mis estudios, sino que pude comprar una computadora mas moderna con los accesorios que siempre quise. Ahora, despu�s de 5 meses, estoy listo para intentarlo nuevamente. Llegar a los $50.000.- DEPENDE EXCLUSIVAMENTE DE VOS !!!. Deber�s dejar este art�culo en todos los lugares. Donde se te ocurra.

Veamos nuevamente las razones por las cuales debes hacer esto : El �nico costo son 5 dolares y 5 estampillas para enviar los sobres. Luego simplemente mande su art�culo por cada hueco de Internet (CON SU NOMBRE, POR SUPUESTO). Ahora si�ntese (ironicamente) y espere a que lleguen las cartas. Ver� que invirtiendo 5 dolares, y un peque�o esfuerzo, OBTENDRA RETORNOS DE $15,000 A $25000 EN UN PERIODO DE 3-5 SEMANAS ! ! !. POR LO TANTO, HOY NO JUEGUE ESOS NUMEROS A LA LOTERIA, O COMA EN SU CASA ESTA NOCHE PARA NO IR AL Mc. DONALDS, E INVIERTA ESOS 5 DOLARES EN ESTE SISTEMA AHORA !!! NO PUEDE PERDER ! ! !.

Qu� es exactamente lo que hay que hacer ?. Aqu� me encargu� de dejar todas las instrucciones detalladas de la manera mas sencilla. ENTONCES, ESTAS LISTO PARA GANAR DINERO !!!??? AQU� VAMOS !!!

*** LA LISTA DE NOMBRES ESTA AL FINAL DE ESTE ARTICULO ***

Bien, lea esto correctamente. Ser�a bueno que imprimiera esta informaci�n.

INSTRUCCIONES

1. Tome un trozo de papel, y escriba en �l : "Please add my name to your list". Esto es lo que hace que este sistema se legal. Porque no estamos enviando un d�lar a cualquiera en forma aleatoria, sino que se lo enviamos a alguien que nos est� prestando un servicio. Aseg�rese de colocar con letra legible su nombre y direcci�n completa.

2.- Con este trozo de papel envuelva el billete de un d�lar, coloquelo en un sobre, y env�elo a una de las cinco personas listadas.
Es importante que el billete quede envuelto para asegurarnos que la carta llegue a destino.

3.- Ahora lea atentamente, as� es COMO VA A LLEGAR SU DINERO. Vea la lista de 5 personas ; borre el primer nombre de la posici�n 1.
Ahora mueva hacia arriba la posici�n de cada uno de los cuatro restantes. O sea que el nombre de la posici�n 2 ahora va a la posici�n 1, la posici�n 3 a la 2, la 4 a la 3, y la 5 a la 4.
Ahora coloque su nombre, direcci�n, c�digo postal y PAIS en la posici�n 5, la �ltima posici�n de la lista.

4.- Ahora mande este art�culo a todos los lugares que se le ocurra (Newsgroups, Boletines locales, Areas de mensajes y archivos, BBS, etc.).
Col�quele al art�culo una descripci�n llamativa, como : NECESITA DINERO RAPIDO ? AQU� ESTA !!!, o GANE 50000 EN 4 SEMANAS !!!, etc. Cuanto mas se distribuya, mas dinero ganar�.

5.- Si necesita ayuda y no sabe dejar mensajes, consulte con el sysop
de su BBS. Dentro del ámbito de Internet siempre encontrará personas
dispuestas a ayudarlo. Aconsejamos alquilar una Casilla de Correo.
La cantidad de cartas que van a recibir es realmente importante.

LA HONESTIDAD ES LO QUE HACE QUE ESTO FUNCIONE.

The contrl grid of the 250 is too fragile, and grid spacings are not correct for zero bias GG operation. You can use the tube cathode driven, but will still need screen and bias voltages.

The screen must be very well regulated, or IMD will be unpredictable.

Three or four hundred ohms of grid swamping is too high, unless you plan on driving the tubes with less than a few watts.

Any zener around that voltage will work, cahanges from 5 volts to 10 volts
will make no measurable difference in SB 230 performance.

If the zener is bad, you likely had a tube flashover. I'd add a 25 to 50
ohms 50 watt high voltage energy dissipating resistor in the anode path.
It will protect the tube and zener in case of a momentary tube fault from
gas.

> The subject says it all.
>
> Is there a negative resistance region in these diodes, as in
> tunnel diodes ?

Gunn diodes do indeed exhibit negative resistance. If you plot voltage versus current it starts off linear, then levels out and goes downward with increasing voltage (the negative resistance region) and then goes back up again.

The diodes themselves are made out of specially doped gallium arsenide. They are called diodes because they have two terminals, but have no rectifying properties. The negative resistance comes from the presence of two conduction bands within the semiconductor lattice - you might think of the atoms being in small pits, with hills between them. To move an electron between atoms, you need to push it up out of one pit and let it fall into the next.

The way things work out is that there are two possible paths between atoms, with different energy levels and different electron velocities. Initially, the electrons are in the fast paths. By applying increasing voltage across the GaAs, thus increasing the electric field inside, electrons start to move to the slow path. Slower electrons means fewer electrons passing a given point, which means lower current. Thus, negative resistance. Couple this to a resonant cavity and you gave a Gunn oscillator.

There is more. You'll find details in all the usual references.

705. Adding AM stereo to a digital tuned AM reciever, using Sony SRF42

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-26 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDwqAMr.FGq@netcom.com>
Source record: 102971

AM STEREO modification of digital AM/FM stereo receivers, using a Sony SRF42 AM stereo walkman radio chassis

You probably have a stereo FM/ mono AM receiver for your home stereo system. And it probably is a PLL digitally tuned radio, maybe even tunes up to 1700KHz. But still mono. It's nearly impossible to find an AM stereo set, the only one you can hope to find is a portable, a Sony SRF42. But it's analog tuned, but it is possible to use the innards of this Sony to demodulate AM stereo signals tuned by your PLL digital mono set's front end. Idea is to disable the Sony's front end, and feed the IF (intermediate frequency) from the PLL digital circuit to the IF amp section of the Sony. And take the left and right outputs and substitute those in your reciever for the mono AM signal.

This is not a project for beginners, you'll need some experience with radio circuits and fine soldering.

Before you tear into the SRF42, tear into your receiver, and look for the AM circuitry. Probably a chip. Helps if you have the service manual. Look for a small squarish plastic part, probably colored orange. Hopefully it has a marking like "450". Other shapes these filters come in are a rounded brown 3 leaded thing, marked "450" (AM) or "107" (FM). The IF frequency of the AM section needs to be 450 KHz, because that's the frequency used in the SRF42. Other IF freqs used are 455KHz, which is too much of a mismatch for the below to work.

Open up the Sony SRF42. First, remove the volume control knob (pulls out). No need to remove the tuning knob, and don't try to remove the on=off switch knob. unscrew three screws, and the front comes off. Unsolder the battery connections to then be able to remove the radio's circuit board. You'll see a plastic gear that controls the tuning capacitors. replace the volume control knob on the volume control shaft (so you can vary the output level later). Now for the interesting part: connect a jumper wire across the AM local oscillator coil, located next to tuning cap trimmer CT4. Jumper goes from ground to the pad connecting the coil to the tuning cap. This disables the Sony's front end.

Now connect a small cap (about 0.01 uF ceramic) to the SRF 42 at this point: Look for pin 12 of IC1, and follow the pad to R26, the point you want to connect the cap to is the pad on the other side of R26 away from the IC1. Keep the leads short on the cap. Connect a length of shielded wire to the free end of the cap, and the shield connects to a 0.1uF cap, and that connects to a local

ground (look for the connection of the metal shield of a nearby IF transformer). Purpose of this cap is to provide an RF ground, but to block DC and audio frequencies.

At the other end of the shielded cable connect a 1K resistor to the center conductor. Now you will need to do a bit of poking around in your reciever with the power on, and power up the SRF42 and listen with headphones (you should only hear some hiss, no stations). Tune a local AM stereo station on your reciever (though your reciever only gets it in mono now). Look around the above mentioned IF frequency modules you checked before you took the SRF42 apart. Now tune the volume on the reciever down, and the SRF42 up some, and start poking around with the 1K resistor attached to the cable. Oh yeah, connect the minus power terminal of the SRF42 to the reciever's ground. Poke near modules marked "450" and you should soon hear the SRF42 playing the station you tuned the reciever to. Try a number of locations and note which sounds better (less distortion, a reasonable amount of high audio freqs, and when you select a point, check a few other stations. When I selected a point to tap, I connected a 1K resistor to the top of a 1K trimpot, the other end grounded, and the wiper feeding the cable. Then I could tweak the level for a reasonable signal, decent signal to hiss, vs distortion if the signal gets too strong. If the point you selected has a DC bias on it, use a 0.01 cap in series with the 1K resistor to avoid loading the DC.

To power the SRF42 "chassis", I used a 5V regulator chip, and the 5V output I passed thru a large red LED and the other end of the LED connects to the plus power terminal of the SRF42. Which should be about 3V (2V drop thru the LED).

To cut some of the high frequency audio hiss and noise, I connected 0.015 uF caps to ground, and the other end of one to a pad connected to IC5 pin 2 and the other cap to pin 4. A more convenient attachment points are located just under the volume control. Not the pot connections themselves, but look for 2 pads closer to the board edge that lead to the IC5 pins 2 and 4.

I just connected the headphone jack to the audio amp, and used the SRF42 volume control to set a reasonable and undistorted signal level.

>--
>Gary Coffman KE4ZV

Well said, as usual. Thanks Gary.

IMHO, the use of CW will not entirely die out, in the same way that old crafts and customs are carried on by enthusiasts. To this day we still have equestrian activities (did the automobile spell the end for the horse?), archery, calligraphy (is calligraphy a reaction to standardised letter writing?), blacksmithing, model steam loco building etc. etc...the list could go on.

There are many remarkable things that persons do for the simple pleasure that the challenge brings. Jumping from heights with a parachute, climbing cliffs and mountains etc. They don't have to do these things- the challenge is the big attraction.

Well, for some, it's a bit like that with CW. The magic is right there; what, with a few home-made items, it is possible to get in touch with some-one on the other side of the world- no satellites, no metallic connection, no fancy electronics, just an antenna and the ionosphere. And all the coding and decoding is done in "in the head", complete with nuances, laughter and so on. To me, that is the challenge.

I spend my working day surrounded by hi-tech communications hardware and guru's. To use CW is just plain enjoyment. However, not for one moment would I force it upon an uninterested person.

73, Kind Regards, Drew, VK3XU. Telstra Research Laboratories.

The reason for rot13 is not to encrypt a file to keep unwanted recipients
from seeing it. It's just a way someone can post something which can't
be read accidentally. Like posting a joke which someone might find
offensive to a humor group. If someone is just rifling thru the jokes
they won't be offended unless they deliberately decode the rot13.
Another use might be for a post which "spoils" or gives away the plot of
a book or movie.

Gary,

I do believe you missed my entire point. Ham radio is more than RTTY, or ATV or SSB or CW. It is all of the above. Because a large number of hams use CW, it should be included in the testing, in my opinion.

I stand by my argument about the HF bands. I'll offer one more argument. If the HF bands are such a valuable resource for high speed communications, why isn't the FCC planning to auction HF spectrum?

Could it be that commercial interests know that you don't get enough bang for the buck on HF? Foreign broadcast encroachment is our greatest threat for our HF bands, not commercial high speed digital services.

No doubt there are many foreign hams who are affluent enough to purchase fancy ham gear of all types, but I have communicated with many who are operating homemade gear, both receiver and transmitter. Others were using converted military or commercial surplus.

73,

Jim

Hi Carl,

try K2AW "Silicon Alley"
175 Friends Lane, Westbury, NY 11590
516-334-7024

His prices are reasonable, and service is excellent. I've bought
zeners for my SB220 from him. He had 'em in stock.

Agreed.

Nitpick: the term should probably be "negative differential resistance" or
"negative incremental resistance", for both Gunn and tunnel diodes, since
the slope of the I-V curve is always positive. The "negative resistance"
region is that over which the resistance _decreases_ for increasing bias,
but it still remains positive. (It's possible to use active devices to
construct a negative resistance (or impedance).

Gunn diodes are used in oscillators at microwave frequencies.

Yeah, a Gunn diode is a sort of cousin to the tunnel diodes. There
are substantial differences, though. Basically, you stick them in
a resonant microwave cavity, apply a voltage within a certain range
and they oscillate.

I always thought the HF wasn't used in commericial applications because
of the antenna. Who wants a pager or cellular phone with a 40ft antenna
;^>. Besides as someone who is learning morse now I think it will be fun
and should stay a req. but I also think some digital apps would be fun
to mess around in too.

Amplitude Compandered Single Sideband (ACSS) received considerable
experimental status about 1976-7 when the topic made two covers of QST.
I still have some of the original equipment. It was promoted in the
amateur radio community primarily as a spectrum-saving new mode. A
better presentation would have been as a mode with a 12-15 db better
signal to noise improvement. Our amateur radio community might have
perked up a bit more. So, it sort of faded after the experiments.

But Tom Lott, of Hong Kong (?), who wrote the original algorithems and
base-band conversion circuits became disenchanted with the amateur radio
experimental scene, I gathered, and sold the concept to the Chinese
government to use as their government radio system. I lost track of Tom
after that.

Also, about that time E. F. Johnson acquired some rights to produce a radio that their marketing department decided to dub amplitude compandered single sideband and introduced a new concept for business band VHF radio, using repeaters (or translators). They were advertised on the basis of a system that would double the range of existing FM repeater systems using the same frequency and tower height. Again, another marketing fault.

When the system would not talk any farther than regular FM, albeit with a better signal to noise radio at the radio horizion, the system flopped big time.

So it appeared that a new technology, a really desirable technical radio communications mode using digital technology failed due to non technical reasons. It happens; no doubt you can think of other technical systems that were displaced or never got off the ground due to non technical reasons.

My recollection may not be entirely complete and perhaps someone else closer to the manufacturing or engineering aspects of the mode could contribute some interesting comments. This is a wheel that does not need to be reinvented, just pulled out of the barn and dusted off! One of the technical problems in 1977 was the lack of digital LSIC that were able to survive the r.f. environment and avoid RFI.

Hi Fred, according to Ed Hare on "Ham Radio and Moore" :-) either the
FCC or ARRL will be publishing a worksheet/checklist that will take about
an hour to do, and will show whether one is safe, unsafe, or borderline.

Wouldn't a typical case for an amateur set-up be one in which
the result is at least divided by two as a result of the typical
amateur QSO being a 2 way communication with an average
duty cycle being 50%?

Additionally, for general public exposure, it would seem that
most situations would result in even lower exposure levels
because of movement by the "public" through an area
as opposed to sitting in one place. Granted there may be
some exceptions to that, but I can't think of any at the
moment.

In another post, Clay N4AOX said:
> Hmmm, based on what you say, it seems that other thinkgs being equal a
>low duty cycle mode like Morse OOK CW would be provide a lower exposure
>to operators and the public when averaged over the same amount of time
>than say an FSK mode. In other words Morse code, among other positive
>attributes is more healthy than some of the newer fad modes. ;-)

That too would improve (i.e. leesen an otherwise high or excessive
value that might be generated by calculation). As Clay notes,
CW is not a continuous transmission, so a duty cycle for transmit
only can probably be fairly easy to calculate. On that same
basis, SSB transmissions do not contain the Peak levels
except at certain speech patterns, so some average value
or correction factor would be helpful when calculating SSB
averages.

Nine stations surveyed is not anywhere near a statistically significant
sampling. Further, the findings were not used to provide any exemptions
for scenarios which did not exceed the regulation.

Most other services received exemptions for particular scenarios.
Amateur radio received none, except the 50 watt PEP output (no mention of
antennas config or EIRP) which is not technically sound.

The 9 station study is/was essentially useless.

This is patently untrue. More and more commercial service are
looking at and beginning to use or reuse HF as a lower cost alternative
to satellite links. Adavanced HF coms functionality like ALE, burst
modems, and FH/SS allow more reliable, higher data rate coms than in the
past. Even with all this technology, the cost is often cheaper than the
satellite route.

Don't be to sure the HF spectrum is safe from commercial interests.

Whether or not the CW requirements should be removed, I believe
more digital comms questions should be on the test. That is, if your
license class allows you to use a mode (digital or otherwise) you should
have to answer questions on it.

It's been a while since I took the tests but I don't recall questions on
any modes, except CW,FM,SSB on the tests up thru Advanced. As I recall,
most of the "advanced" modes were covered in the Extra class exam. This
does not mak sense to me. I'm allowed to run packet, ATV, SSTV, and RTTY
and I don't have to have any knowledge of them?? Is this still the

case??

You've already received some good info. One other thing to
remember, you should also modulate the driver stage to improve the
modulation linearity and peak modulation cpapbilty. For complete info,
see Lenk's book Solid State RF Design.

If the output transistors can take it, you should get at least
twice the power output vice linear mode.

A friend of mine is a radio amateur and he has got this transceiver
radio:
RTX mark ALINCO
ELECTRONICS INC. JAPAN
Portable VHF
model DJ180E

He has got two questions about this radio:
1) How can he modify his radio to extend the band from 144/146 MHz to
130/170 MHz?
2) Can he receive the "manual for use" of this radio? (A photocopy of
the manual is acceptable too!)

For details, please conctact me through my personal e-mail address.
Thank you very much!

You also need to modulate the driver, because of high feedthrough power and failure of the transistors to follow square law rules over a large collector voltage range.

Without modulating the driver, the audio will be distorted and 100% modulation on negative peaks can never be reached.

Be sure the transistors can take the peak collector voltage of signal plus audio plus SWR.

For linear amplifier operation, you neeed to set the impedance for a conjugate match at the maximum power output level, and then reduce drive. You will be darned lucky if the devices allow a 4:1 ratio to be enough for good linearity and safe power dissipation.

>Or maybe a multitude of Japanese models that I've never seen.

Hi Mark,

Thanks for your reply. The thing with your suggestion is that it would be ok
in the shack, but as I have linked the RF output from the satelitte receiver
to the antenna system of the household, via splitter/combiner's, it would
not allow me to see the converted PAL in the rest of the house.

So I need some kit/project/unit that would allow me to tave the VIDEO &
AUDIO from the sockets on the back of the satellite RX and then arrive at
the required PAL signal, hopefully already RF modulated.

either way I appreciated your time in responding.

Not always true.

---------I have seen your posts elsewhere relating to your personal
experiences, it is not friendly to send so much text, however .--------
---
If you stand too close to a functioning radar antenna you will hear a
buzzing, this is because of the instentaneous heating of the brain by RF
that generates tiny shock waves due to slight thermal expansion, the
shockwaves are picked up as sound in the inner ear. This could be the
mechanism employed, would not be of use if the auditry cortex was not
functioning.
Ps dont stand too near! or dont try this at home as they say on the kids
programmes.
There is also documentry evidence that carefully directed varying
magnetic fields can affect mood and vision, the effect must be small as
the fields employed with PET scans are enormous and I have not heard
that patients mention any ill effects.

>not record S-VHS tapes and does not have a built-in tuner.
>

[The saga continues......]

OK, a new multi-standard TV or Video is out of the question, otherwise I would be the proud
owner of one right now, but thanks for the suggestion.

Modifying a PAL telly is also out of the question as the wife would shoot me!

The reason why a dedicated NTSC>>PAL converter is required is that I have distrubuted the
RF from the Satellite receiver into my households TV antenna system, ie

ANTENNA--------- -----TV1
COMBINER-------SPLITTER-----TV2
SAT-RXOUT ----- -----TV3

So it would require 3 new video's or telly's with the multi-standard option.

My only option is now to take the LINE_LEVEL audio & video out of the satelite receiver, run it through a NTSC>>PAL converter and then re-distrubute the re-modulated and converted signal as I do now.

That is why I need a dedicated converter.

I have seen one here in Australia at a satelite company but like always I attempt to
shop around for alternatives.

Again, your input is most appreciated.

I have seen this done but if you do it by just connecting the
grid-1 and grid-2 to ground you will vaporize the control grid.
You can connect the control grid to the cathode and ground the
screen grid. But the output power will be low.
I knew a guy that tried to use series resistors on the control
grid and also tried to tap the control grid down the cathode choke
to reduce the drive to it but neither worked very well.
Eimac recommends not to use triode configuration for the 4cx series
or the 4-65.

Less power and more antenna gain results in the same radiated
signal strength, but as frequency increases, path loss increases the
same amount that antenna gain increases (all other factors
being held constant, including coax loss). So the *same*
power is required.

>>

I cannot TYPE 1125 wpm. In fact, I can send CW faster than I can type!
I'm not even sure I can TALK 1125 wpm.

This is still a HOBBY ... only a HOBBY. It is what you want to put into
it, and the wonderful thing about it is that it is so diversified there
is something for everyone.

There are those who wish only to chat on 2 meter FM with HT's. Fine ...
there's a place for them and I enjoy their company. There are those who
wish to play around with technology ... fine, they have their places too.
I also enjoy reading about that aspect of the hobby.

Some of us (myself included) are DXers, contesters and VHF DXers/contesters who build their own VHF equipment. We have our places in the hobby, too.

The thing is that it is a communication hobby as well as a technology hobby. Live communication. I'm not trying to send a novel to the guy at the other end; I can do that on Internet. But considering my typing speed I don't need to send data at 2500 wpm or whatever; I just want to communicate with they other guy in real time and if I can send CW at 60 wpm, type at 45 wpm or talk at 300 wpm I'll still exchange ideas.

So for those who wish to see how many novels per hour they can send via CLOVER, well - have fun. I still enjoy reading about your results. But I still like those slower forms of communication, CW and speech. They are also fun in this hobby, to me at least. And to a few others ... I've had several one-hour CW and SSB ragchews recently.

Agreed - it's a tube-killer and the intermodulation is severe.

Any tetrode can be used with cathode drive and both grids grounded to
RF, but only if the correct bias voltages are applied to both grids.
Older tetrodes with control grids rated for Class-C operation will
survive with both grids directly grounded, but modern tetrodes such as
the 4CX series will not.

737. External antenna for radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-27 00:00:00 UTC
From: fiz <fiz@lamar.colostate.edu>
Message-ID: <322330B7.1AD8@lamar.colostate.edu>
Source record: 102917

Hi,
I've got a small Rat Shack radio (AM/FM) in the lab here with a telescoping whip antenna. Unfortunately, I'm back in a corner, on the bottom floor, or a steel structure building and have horrible reception on the very few stations I can get. Does anyone have any ideas on how to hook up an antenna (a longwire variety) to this radio that I can toss out the window, without having to make major alterations to the radio itself. I'm considering simply opening the case and soldering a wire onto the place where the whip is attached. I would rather have some type of antenna which would couple to the whip without being permanently attached.

Hi,

Wouldn't suggest soldering a longwire to the place where the whip is
attached; chances are you'd overload. Here in Europe we have a lot of
HF broadcasters on the lower HF bands that just overload everything -
as do the local FM and AM broadcasters.

I've wound a few turns of INSULATED lead in wire around the telescopic
aerial itself; the capacitive pick up gets the signal in but reduces
the risk of overloading; the more turns, the more pickup.

Hope this helps

Joe, G0RNC

>linear amplifier?

1.5 A, or Watts?

If really amps, then big problem is power dissipation (12 + W).

You could use a NPN power transistor. Connect the collector where cathode (stripe) went, emitter where anode went. Now connect a ~7.5V (*), 1 or 1/2 W zener from collector (cathode) to base (anode). thus:

```
|
|
- ->Z-------|
| |
| /
---------- |
|\
\>
|
```

voila! a high power zener. Current through zener is reduced by beta of the transistor... at least 25 for most NPN power transistors, so 1/2 Zener device is fine, the transistor does all the hard work, so heat sink it .

Alternativly, you could go the " Vbe multiplier" route. Replace that zener with 1K ohm 1/2 or 1 watt resistor. Add 50 ohm pot + 67 ohm fixed (1/4 W OK) from base to emitter. Adjust pot to obtain 8.2 V. This will drift more with temperature (lower voltage with more heat) than "zener booster" will.

Both solutions use parts available at Radio Shack. (though you might need to series some zeners to get 7.5 V)

-KF-

* 7.5V = ~ (8.2V - Vbe)

There are some newer products which are on 2.4GHz and use FM video
modulation. I had a chance to play with one (sorry I don't remember
the brand) and discovered they work quite well. They use standard
NTSC pre-emphasis and a 4.5MHz audio subcarrier. You could Hot-Rod
them by adding a preamp to the RX and a power stage to the TX to
make a very good quality video link system.

Sorry Zack, but for the privilege of using CW and speech, you must demonstrate proficiency in the setup and use of CLOVER? What? You say you'll never use it? Doesn't matter, for it is the one true "mode that get's through when nothing else will".

Do try to get the point here. Most of us "un-washed no-coders" agree with you that CW use may be entertaining, charming, even useful, but we are NOT forcing you to demonstrate proficiency in something ELSE to use it.

They didn't intend to conduct a statistically valid poll, nor was there
any intent to offer categorical exemptions (the FCC didn't intend to offer
any until the ARRL put political pressure on them to do so). It wasn't
a survey of the amateur population. All they were doing was getting
some real world baseline engineering measurements of real world amateur
radio stations to see if they conformed to the engineering models used
for field strength calculation. The stations measured were typical of
the real world sorts of stations amateurs operate. The nine stations
measured had a sufficient universe of antenna types and mounting
environments to confirm the engineering models.

In fact standards are lower than that:
The ANSI-95.1,1982, adopted by the FCC in 1985,
limit the peak SAR to 8 W/kg and the SAR averaged over the body to
0.4 W/kg.

For exposure to incident power density, the 1982 ANSI-C95.1
exposure limits are frequency-dependent:
. 1 mW/cm2 at 150 MHz
. 1.5 mW/cm2 at 450 MHz
. 2.75-2.83 mW/cm2 from 824 to 850 MHz (cellular)

Some info on these can be found at URL's below:

One must consider:
What happens when the mic breaks?
What happens when the computer program handling the DSP has a bug in it?
What happens when the TNC dies?
You still have 12 volts from the car battery (the lights went out like they did a weekend or two ago) and the transmitter puts out SOME signal that can be tuned, and the receiver although crude, does still work, then what do you do?

Even with my tech license, I can send a few WPM of CW and could get the message out if I needed to. Maybe I'd need to have the response sent to me slowly, but I could understand it, and I'd be communicating!!

Something to consider....

A couple of my engineering students and I picked up the frequency companding idea and implemented it on the TI DSK DSP evaluation board. It was written up
in QEX a while back. The editors allowed me to put a copy on my web page. You can see it at http://www.wwc.edu/~frohro/qex/qex-art.html. We didn't implement the amplitude compandor, but that could be added in. Our testing indicated that it was a feasible system, but I doubt it will ever catch on, as there are better ways of reducing the spectrum with DSP.

First I'd like to point out that I only wrote the stuff I
"unindented" to
">>" above ...

>I cannot TYPE 1125 wpm. In fact, I can send CW faster than I can type!
>I'm not even sure I can TALK 1125 wpm.

I'm sure the pervious statements are correct ... however, typing in
real time is not the point. If I can buffer up data and "burst"
transmit it across the channel at 1125 wpm, then I only have to use the
channel 1/225th of the time to maintain a constant apparent throughput
of 5 wpm.

This permits time division multiplex multiple access use of the
(same) channel by up to 224 other pairs of users (assuming a protocol
that would allow 100% efficient channel access ... YMMVS)

The protocol could alternatively coordinate the use of the channel by,
for example, 4 users transferring files (to four other users) at 250 wpm
and 25 user pairs doing keyboard-keyboard or other low rate data
exchanges at 5 wpm. (again, YMMVS)

Can you see that, with a little imagination of what's possible beyond
CW, one can invent a lot of other interesting (and useful) uses for the
spectrum?

BTW, one could send CW by key, have the computer convert it into a simple stream of "1" and "0" symbols (or multi-level code it to represent di, dah, letter space, and word space), code that data stream with a FEC EDAC code so that it could be decoded reliably at signal levels at which CW signals could not begin to be copied by ear, transmit it to an appropriate receiver which would decode it and restore it to the audio symbols di, dah, etc. and output the "CW" audio.

"Why?" You might ask.

Because, to illustrate the benefits of spectrally-efficint modern technology in terms the average CW user might comprehend, I'll bet if someone (or a small group) were interested enough in "CW" to take the trouble, they could design (assuming they had the requisite technical know-how) a protocol/modulation/coding scheme that would support this hypothetical type of "CW" virtually error/interference-free at an occupancy level of something like 2500 simultaneous 20 wpm QSOs in a chunk of spectrum no bigger than the 20m CW sub-band.

Assuming a conventional receiver bandwidth of 500Hz, that same 150kHz (last time I checked) sub-band would only support 300 simultaneous non-interfering QSOs using conventional CW (and that's assuming, VERY gratutiously, that those conventional receivers had ideal, "brick wall" filter response).

Let's see, that's 2500/300 = an 8.33:1 efficiency edge for the digital "CW" crew ...

>The thing is that it is a communication hobby as well as a technology

Again, the advantage is not necessarily sending it faster so you can send more, but sending it faster so you can "go away for a while" and let other folks have a crack at using the same spectrum ... it's another form of efficiency.

>So for those who wish to see how many novels per hour they can send via

>

Fine ... multiplex your "CW" bits in with the others and rag-chew all you want ... just don't force me to do it ... I'd rather use my bits in other ways.

If we don't use our spectrum more efficiently, we'll lose it to those who will invent more efficient, productive used for it.

>to just 1.38 meters, and for uncontrolled exposures to 3.15 meters.
>That's much better.

Although the FCC report and order says nothing about the near field
problem when calculating HF limits, IEEE C95.1 1991 says in a 'note'
to the tables for controlled and uncontrolled that the MPE is the rms
E and H limits given in the tables. Thus, IEEE C95.1 1991 essentially
tells you to use the far field values. In the case of your isotropic
example that uses 100W ERP, E= 1842/f or 61.4V/m and H=16.3/f or
54A/m for controlled exposures. This yields a radius of .89m for E
and .27m for H (whether near or far field). For uncontrolled, E
=823.8/f=27.46 V/m and H=the same as for contolled = .54A/m.
This yields radii of 2m for E field in uncontrolled and the same .27m
for H in uncontrolled.

Note that when doing the power density calculation, f**2 should be
used, not "f". When calculating power density for the 3-30MHz range,
the power density is the same E field 1mW/cm**2 mentioned on the ARRL
website. The H field power density limit is 10000/f**2 or
11.11mW/cm**2 for controlled and uncontrolled. You will obtain the
same radii for E and H using the "S" for E and H (power densities)
column as you do when using the E and H field columns in all cases.

Using the isotropic antenna at 100W ERP, the standard tells you to
stay .89m away from the isotropic antenna in controlled environments
and 2m away from uncontrolled environments. With a real dipole type of
antenna, the hotspots will be the feedpoint (H field) and the

endpoints (E field). Theoreticaly, the distances should not exceed the worse case example of the isotropic antenna. When adjusting for 1000W ERP, the radii do not increase by 10 because it is a SQRT relationship, so the distances are not as high as one might initially think.

Although the calculation is easiest to make on an isotropic antenna, I have not been able to find or build a good one ;)

I have made 'em work pretty well...sometimes. Had to re-match input by carefully controlling the (a) coax length to the input. With many lengths, I got no pwr out. Certain other lengths gave near full output.

Most feel that conversion is sooooo much work it's not worth it. Gotta add t/r switching (from full duplex), probably change some filters than can't be tuned, and do an awfull amount of software rework.

Gary:
I have a copy of the report on my desk. This report amounts
to just a lot of measurments. There was no calculation of fields strenghts,
then the confirmation of these calculations. Far and Near fields were mixed
together and no organized approach was used. If fact when I was in school
if I submitted a report such as this I would have received a grade of "F".
On the first page it infers that this is a product instigated by one Dr.
Wayne Overbeck(a concerned citizen) whos qualifications or political
affiliations aren't mentioned. Somehow the FCC took Wayne Overbecks
word verbatum and put into law. The title "concerned citizen" is from the
FCC 96-326's discription of Wayne Overbeck. Interesting.
It sure would have been nice that if the time that was spent
taking
all the measurments were coordinated using known and accepted Engineering
principals. The 50 watt limit is right off the top of one Wayne Overbecks
head is completely without scientific validity. The commercial limits were
only set as to not upset existing installations the 1KW ERP limits are just
as invalid.
Congressional mandate requires that rules be valid and

scientifically
defensable to be written into law. This issue demands good science as the issue of hazards need to be resolved, not the advancement of political causes.
Amazing was the fact that the issue of RF burns was only given passing mention. The issue of induced currents into house AC and Phone wiring wasn't considered even though it in some of the cases influenced the value of the measurments. There needs to be a study made using accepted methods to obtain real data as to the field strengths in the various installations. This should have been done before the ARRL submitted their comments. The ARRL has set themselves up as the voice of Amateur radio yet they have done little else than appoint a committee. Hey, folks this issue came up more than 10 years ago, lets not rush into anything.

Cliff, W7VVA

I am painfully aware of this right now. It seems that you need access
to test equipment if you're going to do much more than the simplest QRP
rig, which seems to make it out of the question for a no-code tech.
I've
built my own packet modem, battery charger (switchable between NiCd and
gel-cells), two logic probes, numerous attempts at dual-band antennae
(with a fixed-station winner described to me over the air by WA6TVM, and
my preferred mobile described over coffee by N6FRI), two headset mikes,
a 2 meter "tin can" filter, various other projects which don't work well
enough to mention, and homebrew AX.25 and APRS software. Maybe i could
build a Ramsey transciever or a Hamtronics receiver/exciter, but without
an elmer with a scope and/or spectrum analyzer, the most that i can do
in the RF realm that i could use would something like a 10 meter
receiver
for RS10/11. Otherwise, i have no way of knowing if i'm complying with
Part 97. I've looked on the WWW at (but not asked about) local clubs
for folks who could help me get started in RF, but so far i haven't seen
anything encouraging yet. I guess i'll have to ask around on the local
nets. Otherwise, i first major project might have to be a scope built
out of TTL and one of the new fast ADC chips. (That would be *much*
easier for me to design than a simple QRP rig, especially if i dig up
a wirewrap gun somewhere and since a recent review of the Radio Shack
$99 digital scope was so discouraging.)

So, you're very right Gary [as is usually the case], that it isn't the
way to get into ham radio, unless someone nearby has the time and equip-
ment to do alot of elmering, like in the old days. When i first tried to
get my license 30+ years ago, that was definitely a way to go. But i'm

afraid that went the way of the vacuum tube AM radio. Fortunately, i could afford a decent HT at the time i finally got my license. But since then, other things have been more important than a well-paying job (such as burnout and avoiding the stress of such a job) and so now i have too many deferred expenditures to consider throwing money at the problem. I could probably be on the air with HF packet/RTTY in a matter of a few days but that's not a choice that i have.

So what are my options? Is there much that one can do in the RF realm without a lot of money or learning CW first? [And, though i continue to try, CW advocates should take note of a mild head injury that has affected
my short-term memory, my hardwriting under stress, and causes me to make strange typos and mix words up. That, at best, makes that even more difficult than when i was of the age that learning foreign languages is considered easy.] I have many ideas to explore higher speed packet, and the software and digital experience to make it work, but without money or
bench access, it seems like there's not a lot that i can do. I sure hope
i'm wrong and someone like KE4ZV can straighten me out on this!

-- KD6PAG (networking old-timer, RF newbie)

P.S. Speaking of which, anyone got a 29 MHz VXO design that'll vary 40 and 100 KHz that i could use with a miniR2 (or a better approach)?

: power is required.

This isn't quite the whole story.

Traditionally, "path loss" is defined between two isotropic, or at least *electrically* constant aperture, antennas. This gives constant ERP but diminishing signal; thus the 'loss' misnomer. However, conservation of energy is not violated and no signal is actually lost, the far end just doesn't catch it all.

As soon as a *physically* constant aperture antenna is subsitutued at one end of the path, recovered signal is constant with frequency. However, if constant physical size isused at *both* ends things get *better* with frequency at the rate of 20*log(F). Thus LESS power is required as higher frequenies are used.

Seem my www pages (under ARRL conference papers) below for details.

>
> "Single-chip Frequency Converter"- Covington, Radio-Electronics Apr. '90.

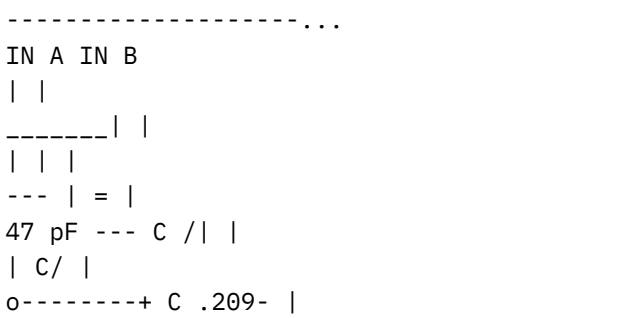
Several existing projects using the NE602 include

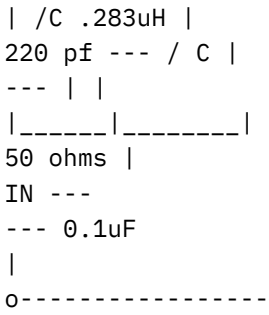
"The Neophyte Receiver", QST, Feb. 1988, pp. 14-18
"W1AW at the the Flick of a Switch, QST, Feb. 1993, pp. 56-57 [$30 kit]
"An Optimized QRP Transceiver, QST, Aug. 1980, pp. 14-19 [or see "The
QRP Three
Bander Transceiver for 18,21,24 MHz", pp. 30-19:25 in 1993 "ARRL
Handbook"]
"Sudden Receiver", 73 Magazine, Oct. 91 [also available as a kit from
Kanga]

The Handbook also says:

The input and output networks can be either single-ended or balanced
for AC. The input and output impedences are about 1.5K for the single-
ended configuration and about 3.0K for the balanced configuration.

and shows a example matching circuit for 45 MHz





The "Neophyte" just uses a cheap 7:1 FM broadcast IF transformer for its input, and there's a several section input filter on the W1AW receiver.

That may not be what you were asking for, but perhaps someone else might find it helpful. One thing you may want to consider, particular if you live
in/near an urbanized area is that you will probably want some kind of input
filter, as i understand that the NE602 is prone to being overloaded by strong signals in adjacent bands compared to mixers such as the SBL-1 (which lack an internal LO).

As a gate, CW/morse, is as universally fair(or unfair) as one can get.

But, if one agrees that some sort of gate is needed then what better
than morse. There is even a work around in place for those who can not
learn it.

IMHO ones respect for a priviledge is proportional to the work required
to obtain it.

>I cannot TYPE 1125 wpm. In fact, I can send CW faster than I can type!
>I'm not even sure I can TALK 1125 wpm.

I am uncharitably driven to repeat the Morse proponent's cry
of "Practice!" in response to your reported low typing speed,
but I'll try to give a better answer than that.

Yours is a common reaction. If it didn't overlook several important
factors, we'd all we content to use 300 baud Bell 202 half duplex
modems here on the net too since that's equivalent to 450 WPM, and
none of us can type that fast either. We aren't, however, and therein

lies the answer for the need for speed. We can convey much richer content than simple text with a bit of speed. For example, if we are discussing a circuit or antenna with our contact, we can bring up a whiteboard and draw a diagram for him if we have sufficient speed. We can't hope to do that plodding along at 20 WPM. We also typically have canned "brag tapes" that we send to new contacts to let them know something about us and our stations. Letting that dribble along at 20 WPM would take intolerably long.

And there's another side to this as well. IF we truly don't have more to say than can be conveyed in a few minutes at 20 WPM, we can drop our transmit power until the CNR is actually *negative*, and still have enough throughput to maintain 20 WPM text. We can't do that with OOK Morse at all. With Clover, we reach that point with a CNR of -4 db, and with PACTOR II we reach it at -18 db on a non-fading channel. On a poor fading channel, Clover doesn't do so well, requiring about +2 db CNR, but PACTOR II continues to operate at the desired throughput with a CNR of less than -10 db. That's about 20 db less signal than a good Morse operator needs to maintain error free 20 WPM.

Note, a very skilled weak signal Morse operator can detect Morse signals at mildly negative CNRs, but he can't approach 20 WPM when signals are that weak, PACTOR II can. In a time where large outdoor antennas have become difficult to install (due to restrictive covenants, apartment living, etc), where TVI and RFI are a concern (due to a myriad of shoddy consumer electronics co-located with many of our stations), and where the current level of awareness of RF exposure hazards is heightened, a technique which can work well with very low transmit power should be welcomed and fully embraced.

>This is still a HOBBY ... only a HOBBY. It is what you want to put into
>it, and the wonderful thing about it is that it is so diversified there
>is something for everyone.

I grind my teeth every time I see that "only a HOBBY" line. We are amateurs voluntarily, self-selected by free choice, and we enjoy what we do, but it is more than "only a HOBBY". The service has chartered purposes for us to fullfill. That differentiates amateur radio from playing golf or from collecting stamps. Those latter activities *are* "only hobbies", but amateur radio is more than that. We are chartered to self-train in the radio arts, further those arts, provide public service and emergency communications, and foster international goodwill. We can, of course, have fun doing those things. That is our only reward. But puttering in a backwater of radio technology isn't fullfilling the first two elements of the charter very well, and could be impairing our ability to fullfill the third. The amateur radio operator's Code (ARRL) says "An amateur is progressive". We need to think about that once in a while.

>want to communicate with they other guy in real time and if I can send CW
>at 60 wpm, type at 45 wpm or talk at 300 wpm I'll still exchange ideas.

Yes, you can, but you can also do better than that. You can exchange more ideas, or exchange them more clearly and fully, with better techniques. You can also reduce the RF pollution on the bands, thus allowing room for more people to do likewise by reducing the power necessary to communicate. If you really only have a few hundred words to say to another person, you can do it in a couple of minutes instead of an hour, thus freeing the spectrum for others to enjoy, or allowing you to interact with more people in a given amount of time. There are many reasons why you might want to use speeds greater than your personal typing rate, and to use techniques which require less power and bandwidth than other methods to boot.

The Amateur's Code says we're to be progressive, but it doesn't say we have to be progressive every minute. We can use older slower less efficient and less effective techniques from time to time if we get enjoyment from doing that, but we shouldn't turn our backs on better techniques in the process. We should be educating ourselves in modern communications theory and practice as an ongoing matter of course. We should be able to recognize that there are other and better ways of doing things than the methods we've used in the past. And we should be able to do some of those things too from time to time.

As you note, not every amateur needs to do everything. There are a multitude of things to do in amateur radio, and many of them have value as well as being enjoyable. As amateurs we have diverse interests, but we should all have the charter purposes of our service in sight as desirable goals to be pursued. That doesn't mean we all have to become (moderately) high speed digital operators, or dedicated ARES operators, or rabid goodwill ambassadors, etc, but we should be extending ourselves in some direction constantly, and not just be stagnant backmarkers filling up space (and spectrum) without any real purpose or direction.

The Army's recruiting posters proclaim that it is "Not just a job, it's an adventure." We should approach amateur radio the same way. It is the best hands-on learning laboratory to which we're ever likely to gain admission. We should take full advantage of it. We're never too old to learn new tricks, unless we let our brains fossilize by going over and over the same ruts day after day. There's nothing more

exciting or enjoyable than gaining a fresh insight, or mastering a
new technique. New ideas serve to blow out the cobwebs and sharpen
the intellect.

Although the phone company only guarantees you from 300 to 3000 Hz, I have consistently found that the response starts at 0 Hz, rises asymtotically(sp?) to 300 Hz, and is then rock steady to 4,000 Hz where it drops instantly down to nothing.

I work in L.A., CA. I don't know about places like Florida, with the worst reputation.

Last time I checked, no one is forcing anyone to USE CW - just learn it. I stand by my original opinion that Amateur testing should encompass the hobby from A to Z. That means that RTTY, CLOVER, PACTOR, and CW all should be included, even if perhaps the former have a smaller following than CW.

Besides, the VHF and UHF bands, were CW is less frequently used, are the ones being threatened, not the HF bands. I don't consider the threat to the VHF & UHF areas to be a valid argument against CW testing, since those areas are already open to those with a no-code license.

I like directional antennas! Cut extraneous noise, boost signal.

It depends on what and where you want to receive. My brother's local radio station which carried his baseball team on AM dropped coverage so I built him a loop to pick up a station about 80 miles away. Works great during the daylight but at night too many other stations come in. We built it out of mostly a bunch of old RG58 laying around.

It's easy to build inexpensive directional antennas for FM also.

ARRL Antenna book is very useful.

772. Bandwidth of a 14.4 (or 28.8) modem?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-28 00:00:00 UTC
From: jpaulino@planete.NET
Message-ID: <199608281244.OAA07747@unix12.pressimage.net>
Source record: 102856

The bandwith for 14.4 and 28.8 Kbits modems is the bandwith of phone lines : 3Khz. This modems use separate audio carriers. Each carrier change in amplitude and phase. The problem for using this methods on Ham band is that they need " equalization before transmitting...and also full-duplex. If you use this technic on VHF Band, the time to equalize (on half-duplex communication)destroy the avantage of this hi-speed modems regarding to the classic 1200 bits.

773. HF AMP POWER SUPPLY DIODES

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-28 00:00:00 UTC
From: aa6eg@tmx.COM
Message-ID: <Pine.LNX.3.91.960828083441.11115A-100000@tmx.com>
Source record: 102857

I am re-designing a homebrew amplifier that uses 4-400As and
a power supply using a BC-610 HV transformer. (Remember those?)
I discovered that the BC-610 transformer has two taps on the
primary, allowing 2500 volts, ac, or 3000 volts AC at the output.
The 4-400's work more efficiently at the higher plate voltages, and
I want to implement a HV increase. I have a roller inductor, which
will allow adjustment of the PI Network output impedance for the
increased plate voltage. Currently, the 2500 volt tap produces 2700
vdc unloaded, and 2500 VDC loaded. The power supply is a Choke
input, full wave, using two diode blocks, made by Diodes, Inc.
Model number 7030. I would like to know what the voltage and
current ratings of these diodes are, to see if they would take the
increased voltage from the PS. Any help?
Thanks, de Pat, AA6EG, aa6eg@tmx.com

Hi All,

I would like to build a power inverter for mobile use. I would like
to be able to convert 12v DC to 120 vac at around 2500 watts output.
Although I have some experience designing and building regulated DC
supplies, I am not familiar with inverters.

I would appreciate any suggestions on books or other sources of schematics.
If there are kits available, that information would be welcomed also.

Please email direct.

Thanks,
Jon KN4AE

Some time ago I started collecting parts for a Field strength meter I was going to build from a magazine article. This got put aside and now I cannot find the magazine article. This meter operated over several decades as I recall and used matched diodes for rectification and feedback around an op-amp to get linear results down to millivolts. Does anyone recall the magazine or year------I think it was QST or 73?

Thanks

You GOTTA be kidding! 2500 watts from a 12v battery? Minimum of
260A draw? Maybe, if you are prepared to carry around about 1000+
pounds of deep-cycle marine batteries for a very few hours of operation
(if that).

Hello

I am wondering what the best aproach to an outside homebrew scanner antenna
is? I'm haveing trouble picking up the 45 Mhz band, but i would like to
recieve all bands? I have a couple of other questions too. One what is
the impeadence of a scanner, and do i need to match that with my coax?
Two if i build an antenna for transmitting and recieving on the specific
wave,, i.e. 1/4 or 1/2 wave for the specific frequincy is it necessary
to load that antenna, with a coil?
Thanks a bunch
Robert KB0PED

The NE602 (and it's derivitives; SA602, NE612, A, AN etc.) has been around for about six years . Although not a particularly "strong" mixer, the easy implementation, coupled with low power supply requirement has made it a deservedly popular chip. It can provide "adequate" signal handling characteristics in receiver applications in all but the most hostile environments (see below).

It would be difficult to derive a table or quick reference for the many coil combinations that are possible. However, much valuable information on the '602 may be found in;

"NE602 Primer"- Carr, Elektor Electronics Jan. '92 (has formulas for calculating oscillator coil values etc.).

"Simple Receivers from Complex I.C.'s"- Parrott, Ham Radio (USA) Dec. '88.

"Using the NE602"- Zavrel, Technical Correspondence, QST May '90.

"Using the NE602 in Ham Circuits"- Carr's Corner, 73 Amateur Radio Feb. '93.

"Single-chip Frequency Converter"- Covington, Radio-Electronics Apr. '90.

Two things not specifically mentioned in any of the above; when using the '602 in direct conversion receivers (particularly where an RF amp. is used); much improved performance will be had if the internal oscillator is not used, but rather, use a separate metal- boxed VFO (when using the internal osc. it is difficult to keep the osc. signal from entering the input of the RF amp., causing "tunable hum" and other unwanted effects), and, contrary to some reports that the '602 is rather too weak as a mixer, if the builder uses a separate osc., and applies the input signal (at pins 1 and 2) in "balanced mode" i.e. true push-pull, without grounding pin 1 or 2 for RF, and extracts the wanted product also in balanced mode, the strong signal handling of the chip will be significantly improved.

73, Kind Regards, Drew, VK3XU. Telstra Research Laboratories.

retro-fit this tube in any amp that runs 3KV or more with 800ma or more, for full legal output.
Forsale; (2)EIMAC 3CX1200-D7 tubes NEW, (you only need one for the same output as two 3-500Z's) $400
each, or $700 pair, shipped, FIRM!
(1) Peter Dahl filiment transformer 6.3vct @ 30amps. CCS, $60 shipped or $30 shipped (with purchase of
tube)
(1)Silicone rubber chiminey(just like ALPHA) free with tube purchase.
(1)Plate clamp , free with tube purchase.
(2) EIMAC SK-410 "air sockets", free with tube purchase.
(1)Complete retro-fit "kit" ;(1)tube, (1)socket, (1)chimney,(1)clamp,(1)filiment transformer. $430 shipped
FIRM!!
(1)inncomplete kit-- Minus filiment transformer, $400 shipped, FIRM!!

Source record: 102933

I am a fairly good EE who is inexperienced with radio. I'm currently working on a home project which has stretched my knowledge a bit, and I'm looking for a little advice.

What I'm trying to do is take a fairly low-bandwidth signal (0-400 Hz audio) and frequency modulate it. I would prefer to do this at a carrier in the low KHz range. The modulated signal would then be connected directly to a reciever/demodulator by two wires and the 400 Hz audio would be taken out again (no antennas, no transmission circuitry - probably just an op-amp copled to the wires with a cap to drive the signal).

Why would I do this, you ask? The wires I'd be transmitting on have a lot of other signal traffic on them (as well as noise), and I'd like to avoid antennas and big amps for space reasons. On that note, the circuit to do this needs to be very *small*.

If any of you have ideas about how the mod/demod circuitry would work, or can tell me some good sources to look at, I would really appreciate it. I understand how FM works, but I just don't know the down-and-dirty of how to physically create the signals I want.

Thanks much, -Owen Wells

Wouldn't it be substantially better to homebrew a receiver using a better filter than those little brown things? A Collins 300 Z-50 filter can be bought for $6 in Orlando, Fla., and will provide better sound by allowing you to tune either sideband and reduce the noise level 3 dB. The output of this IF section could then feed the stereo demodulator IC (which could be bought as a replacement part) or, better still, a high-level synchronous detector.

I also think that the phase-noise level of most of those synthesizers that mass-market receivers will leave you with a noise like slow, steady rain on a tin roof.

I've thought about this some because I enjoy listening to the cleared-channel
station on 1510 kHz and the local station on 1490 here in Bradenton wipes it out completely. Those little brown filters, 20 kHz from Fcenter only give about -40dB
while I think the Collins is probably on the order of -85 dB. Since I live about 1 mile from WWPR and about 600 miles from WLAC, the difference in signal strength greatly exceeds the rejection of the little brown filter that the Nippon Gakki Co. Ltd. gave me as original equipment.

I'm interested in anything about the old Standard Broadcast band, so thanks for your interesting project.

How are you with batteries? That's about 220 amperes of current
you're talking about pulling from a 12 volt source. A standard
auto battery will last about 30 seconds at that draw. You're going
to need a *serious* alternator on the engine to keep up with that
demand (the stock alternator is 50-65 amps max). Neville makes
a big enough alternator, but it would be cheaper to get a 120 VAC
alternator instead. The copper losses would be much less. The trick
would be holding the engine RPM right to make 60 Hz. In mobile use,
you really need an auxillary engine to do that right. Onan makes
RV generators in that power range.

I am looking for a means to match a series tuned coil with an impedance of 1 ohm at resonance to the imput impedance of a NE602 mixer which is 3k. The frequency range is 30 Khz to 150 Khz. From what I can determine is that this is not an easy match and needs to be extremely compact. Any advice will be appreciated.

<Excerpted>:
> "I'm sure the pervious statements are correct ... however, typing in
> real time is not the point".

Wrong. It is the point exactly. REAL-TIME interpersonal communication requires real-time typing (or keying). Buffering up stuff to send in a burst is not real time QSOing. I have run into AM/PACTOR operators who apparently like to just push buttons, and send 'canned' files, give canned responses to questions never asked, include everything but the kitchen sink in "my station is" canned files, AD NAUSEUM. BORING. These seem to be the ops who want to use the "high speed capability" of the "digital modes" (overused word these days). OOK CW is the original "digital mode", and RTTY, another digital (ie, binary keyed) mode have been with us for several decades now. Often, the operator's typing ability limits him to speeds less than 5 wpm! They are attempting to ragchew on the wrong mode. If unable to communicate at a reasonable rate (give the other guy a break, he doesn't have all night), on keyboard or on CW, then stick to 'phone operation, where all you need to do is push a button and speak. Or, (heavens to Betsy!), work on operator skills (typing or CW proficiency) required for the mode of choice. You don't get there by just spending money on equipment; you have to develop operator skills needed to use it effectively!

Bandwidth comparisons of CW to modes often do not take into account the well-known ability of a skilled human operator to decode signals separated by only a few Hz in frequency, and different in amplitude by many dB (including negative sig/noise ratios less than unity). CW ops, especially DXers, do this often.

Ragchewing for me is to engage in extemporaneous conversation as one would on duplex voice or QSK CW. Kick ideas and thoughts back and forth, etc. In other words, talk to a real live human operator on the other end, real time.

Source record: 102794

Wow! What a teriffic debate I sent careening down the mountain....

The plan I had was to use two RCA 833A's in a push-pull grounded grid arrangement, with the objective of minimum distortion, rather than maximum output. I intend to use a plug-in coil scheme, with doorknob "helper" capacitors on wavelengths between 160 and 40 meters. Thus the split-stator capacitor will not have to be of great size while providing a generous breakover rating. Loading adjustment will be by means of a variable link. 160-15 meter coverage is planned (10 meters...if the band's open, you don't need an amplifier and when it isn't an amp won't do much good anyway. Really the same is true on 15 unless you're trying to out-holler the other lids working a rare DX station.)

The real difference is that the power supply for this amp will provide 3250 VDC @ 850 MADC and only weighs 12 lbs (450 g)!!! It is silent, isolated, regulated to 0.5%, ripple-free as can be. I conceived the idea as a hybrid between a modern VCR power supply and that of the amp in the so-called, "boom-car"...

Thanks for all of the valuable suggestions I've seen go by my CRT. Too bad the Internet will make working DX stations seem quaint...

Leaving aside the issue of PFC supplies, I need to point out that
the APT FET's are rather questionable for ham radio use from both
the broadbanding aspect and the linearity aspect. Certainly, APT
makes no claims of suitability at all, and when I talked to them
about it, they weren't very encouraging.

Now as to PFC:
For the vaccum tube linears in use by most amateurs, one straight
forward solution would be to simply go back to a choke input
power supply. The extra iron added by the choke is somewhat
compensated for by being able to take iron out of the
transformer. Transformer efficiency goes up when PF goes up.

Hi Mark (Aitken)

The only problem with this is that you'll get a 10 hz flicker which will drive you absolutely bonkers. (PAL 50 fields per sec. and NTSC 60 fields per sec.) Unless of course, you use a CCD camera with a 1/60 sec electronic shutter. This will negate the flicker, but is a feature only likely to found on later (and therefore relatively expensive) cameras and camcorders. You are also likely to get *Moire* patterns as a result of the interaction between the phosphor "dots" on the screen and the individual CCD elements in the camera.

An old tube camera with loads of *lag* would tend to smooth out the flicker and not suffer from moire patterning, but the *smeary* results, especially on fast sports action, will drive you mad as well. Additionally, colour performance is likely to be poor.

One other possible solution would be to obtain an old standards converter. These are still likely to be relatively expensive though, not to mention large and un-reliable. But think of all the fun you would have trying to maintain it. Also, it's probably ('cos its old) built without VLSI chips, so with the aid of an oscilloscope and a service manual (essential), you could learn a lot about how the system worked. (But to align properly, you will need access to a colour-bar generator and a vectorscope)

So to summarise your options are:-

1). Build a standards converter.

As Gary said, "this is difficult and expensive." i.e. its impractical.

2). Buy a Panasonic NV-W1 and use it as an in-line standards converter between the output of the satellite receiver and an RF modulator (obtained from a scrap video recoder), the output of which can be fed into your aerial distribution system. This machine would also allow you to record NTSC programmes as PAL on VHS tapes which could then be used in any other PAL VHS machine in the house.

But, as you've already said, "This is too expensive".

3). Modify a TV to accept NTSC (unlikely to be easy) or buy a multi-standard TV or monitor.

This is the cheapest solution but doesn't enable you to watch NTSC around the rest of the house.

4). Obtain or modify a TV as in 3). above, and use a PAL camera or camcorder aimed at the NTSC screen to obtain a PAL ouput, then feed this signal into an RF modulator and feed the RF out from this into your aerial distribution system.

This will work but the results are likely to be poor unless you spend money on a good quality receiver/monitor and camera and even then, moire patterning may be a problem.

5). Buy an old standards converter and use as in 2). above.

Could be fun, but still likely to be expensive.

In my opinion, 2). is the best all-round solution to your problem and is certainly practical. But you've ruled it out on the grounds of cost (fair enough), also of course, there's no *homebrewing*, which was the original point of your post.

So as far as I can conclude, you're stuffed !!!

Good luck with whatever you decide to do.

811. Iambic Keyer, ONLY FOUR PARTS!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-29 00:00:00 UTC
From: Rick Miller <rdmiller@execpc.com>
Message-ID: <01bb95da$a08fac00$060801c1@eng06.digalogsys.com>
Source record: 102805
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc
Body handling: Inline uuencoded payload not displayed: pickeyer.c

Hi all!

I posted last week to rec.radio.amateur.misc that I would be
trying to implement an iambic keyer with a Microchip PIC16F84...

Well, I've actually got a demo up and running! This is too fun.

It's menu-driven, even! You can adjust sending speed and the pitch
of the audible feedback tone. You can even adjust the speed and
pitch of the menu-Morse.

Parts list:
(1) PIC16F84 (used to be called "PIC16C84A")
(1) ColorBurst crystal (3579.545 kHz)
(2) 22pF capacitors
(1) Normally-Open momentary push-button (optional)

Well, okay... this assumes that you've got a power supply
of 2-6 Volts DC available, since it's meant to be built right
into your rig. Typical operating current is under 10 mA.

If you throw in the 'optional' pushbutton, you can reset it
into 'menu-mode' without power-cycling your rig.

As promised, here's the source code so far.

Enjoy!

Rick Miller (KB9OBN) rdmiller@execpc.com

From: lleduc@bak2.lightspeed.net
Message-ID: <81c7cc$14e6.98@LSNT6>
Source record: 102806

My neighbor teaches an electronics class at a local high school and has asked for my advice. His students build projects for class and a popular one is a low power FM (88 to 108 MHZ) transmitter that meets FCC requirement. Most of the circuits available offer poor performance being a simple LC oscillator with no buffering. He would like to find a circuit that offers good stability and sound. He would also like to avoid using a PLL or XTAL multilpier approach as this is beyoun the scope of his class.

The audio section is not a problem. I simply used an OP-AMP for this stage. It's the RF section that's the challange. I've built prototypes using the classic Collpits configuration and NP0 or C0G caps but haven't quite got the stability nailed down.

While I realize this group is primarily for Ham's, I'd like to pick your brains on this one.

Thanks.

I had a few problems actually getting the data sheets from the motserv address but I finally found this:
http://motserv.indirect.com/lit/html/br135a/br135apnotes.html
if you can't get the notes from the web, they'll FAX them to you - it seems to work pretty well (in Canada anyway).
I hope this helps!

815. antenna amplifier troubles

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-29 00:00:00 UTC
From: peter.gabrovsek@guest.arnes.si
Message-ID: <841293422.16525@dejanews.com>
Source record: 102871

Hi,
I tried to built an antenna amplifier to cover losses in
70m cable from neighbors roof.
The amplifier schould amplifie 5 programs (1vhf+4uhf). Unfortunatelly
the signal level of the highest channel is also the lowest (40dB),
so I decided to make a three stage amplifier.All transisitors are
BFR91A.
The result was very bad, because the third stage tends to oscillate.
I suppose that the BFR91A is not capable to drive more high level
signals simultanious.
Could everyone suggest me a better transistor (low cost if possible)
or a design that will help me to watch TV with pleasure again.
Pero, Slovenija

>>ttfn fiz (KG0YG)

Use a small alligator clip with a random length of wire connected to
it. (Experiment with the length of this wire, try one as long as space
allows and if the radio picks up too much, shorten the wire a few
inches at a time.) Attach the clip to your radio's telescopic antenna
and see what happens. You can't hurt anything this way and it may do
just what you want.

817. Microwave Diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-29 00:00:00 UTC
From: maf00861@maf.mobile.al.us
Message-ID: <503lqp$oor@municipal.maf.mobile.al.us>
Source record: 102873

What is the highest frequency you can detect with a simple
microwave diode detector? I'm referring to simply connecting
a diode across a microamp meter.
I've used an NTE 112 Diode (Si, UHF Mixer) with a 50 micro-
amp meter. It's a hundred times more sensitive than the Radio Shack
Microwave Oven tester. The tiny but normal leakage around the door
on my microwave oven generates a 10 to 30 microamp current in
the diode at a distance of two or three inches.
As an experimenter, I would like to get my hands on a
diode that could rectify 20, 50 or even 100 GHZ microwaves.
Are there any commercially available?

Re: Discone Plans:

A design article on discones exists in the June 1955 Electronics Buyers Guide, by J.J. Nail. Reference Sheet, R-27. This article references 3 other articles in the literature, which are:

A.G Kandolan, "Three New Antenna Types and their Applications Proc IRE, 34, p. 70 W Feb. 1946

A.G. Kandolan, W. Sichak, R.A. Felsenheld, "Elecronic Communication", 25, P. 139, June 1948

J.M. Bower, "Discone - 40 to 500 Mc. Skywire", CQ, 5, p. 11, July 1950

Mack Seybold, "The Low frequency Discone", CQ 6, p. 13, July 1950

To summarize the Nail article, Impedance plots show that for Flare angles (the complete inside angle of the cone) between 25 and 60 degrees, SWRs to a 50 ohm feed, of 1.5 to 2 to one, exist until the lower frequency limit is reached, then a rather steep climb in SWR occurs. The lower frequency limit is defined by the length of the sloping side of cone becoming a 1/4 wavelength. Slight variations in impedance occur up through 3F, but are inconsequential. At the upper frequency limits, (5 or more F) patterns and impedance are mostly influenced by the dimensions at the pointy end of the cone, and to a degree, by the flare angle. It appears that best performance occurrs when the cone vertex is as pointy as possible and spaced as close as possible to the center of the disk.
Free space pattern plots in the vertcal plane at the lower frequencies look like a vertical dipole. As the frequency gets higher, the dipole pattern gets squeezed at the bottom quarter, so that it looks like a pair of commas, back to back, at 3F. The gain at the horizon is -3.3 dbd at 3.75F, and - 2.5 dbd at 4.85 F. Someone should use Lewallen's modelling program to verify these early computed plots. I would like to know if you can minimize the numbers of wires you model, to the point of using only a 2 dimensional model, requiring fewer segments of wire, and assumptions being made that the pattern is the same omnidirectionally.
Bottom line is, consider the discone to be about like a 1/4 wave ground plane with an upper F limit of up to 10 times F min. i.e. a discone with a cone length of 20 inches should perform well, from 2 meters to well above 1.2 gHz, if the junction area is constructed properly. BTW, if you are ever in Monterey, contact me, for a

looksee at our 80-10 METER discone, courtesy of the US Army, at our new club station, the former Army MARS station at Ft. Ord. Works DX like gangbusters from 80 through 10 meters.

>Drew Diamond wrote:

>. . . [list of receivers using the NE602]. .

>"An Optimized QRP Transceiver, QST, Aug. 1980, pp. 14-19 . . .

No, the "Optimized" rig used a diode ring mixer (homebrew, but an SBL-1 does essentially the same thing). I don't believe the NE602 was available then, but don't think it would have done better than some of the other mixers I tried. DC receivers are very prone to AM demodulation. That is, you're likely to hear audio in the background, because the rig is demodulating strong AM signals. This is particularly bad on 40 meters. The demodulation generally takes place in the mixer (if you've filtered the mixer output properly), then the demodulated signal is amplified by the large AF gain of the receiver. No other mixer I tried came close to a diode ring in its resistance to this. Rick Campbell came to the same conclusion, as he pointed out in his QST articles. I believe the NE602 was among the other ones he tried. The same weakness aggravates other problems like "peakable hum". I wouldn't recommend an NE602 for a 40 meter receiver, and even with a diode ring, you may need a filter ahead of the mixer which is narrow enough to attenuate the strong BC signals before they get there. I took the "Optimized" rig to England once, and heard AM even with it. After I returned I designed a couple of very narrow filters for the front end. I called them "G filters" and they were published in SPRAT some years ago.

Here on the West Coast, the foreign broadcast isn't as strong as it is in, say New England. Only one evening did I hear AM getting through the Optimized rig. I tracked it down to a private religious SWBC station near San Francisco (about 600 miles from here), KGEI, operating at 7360 kHz. I _measured_ its signal at 100 mV (yes, that's mV) RMS at the station end of my vertical antenna coax!

Have fun!

Hi y'all,

Hand Held Products, a bar code company in Charlotte, NC, is looking for an RF design engineer. It should be someone who really enjoys working on wireless data equipment as there is much development to be done. We have some of the tools of the trade... network analyzer, spectrum analyzers, design software, radiated field pre-test site, etc. which the designer would need to have experience using to acheive the equipment performance goals. Our equipment is currently operating in the 400 MHz to 930 MHz range. 2.4 GHz will no doubt be in our future. Candidate should have a BSEE as a minimum. Please respond to wcs@emperor.handheld.com

Thanks for everyone's time.

Bud, W4HXP

<snip>

Marty,

I've used the headsets from Nady's wired rider/passenger intercom. has
a flat speaker (about 1/4" thick) that slips between your ear and the helmet foam.
You can velcro it in, but I never bothered. From this, there's a flexible boom
with the mic on the end. Foam wind screen on the mic. 3 terminal
mini-stereo plug connection; mic, spkr, common ground. I wired an adapter to go to
my FT530, and also to put a paddle switch above the clutch lever for PTT. I connected
a small 2.2K pot for use as both the PTT resistor, and to try and trim mic gain. Top
of pot to HT, wiper to microphone, bottom of pot to PTT switch, other side of PTT
switch to ground. The pot may not be needed; I did it that way as an in case kind of
thing. With the PTT switch as connected, VOX is theoretically possible, but I
didn't trust wind noise or myself yelling epithets at stupid cage drivers, so I never
tried that.

Works pretty well. I've had good audio reports as long as I talk softly.
(The mic is pressed against my lips in my helmet; easily overdriven.) No complaints
of wind noise; many were surprised to hear I was on a motorcycle. Audio output
is okay; I need to buy a new helmet however, as wind noise is a problem. If you have
a quiet helmet or touring bike with big windsheild, I doubt this will be a problem
for you; I have an 8yr old Shoie GRV and a BMW K75S.

Headset is available for about $25 or so; I've seen ads in the various bike
rags, I think it was Cycle World. Local dealer may have the whole intercom if you want
a look, or JC Whitney has them (I had the intercom long before my ham license, so I
just tried it and it worked okay.)

If you can't find a place to buy, EMail and I'll look up the ad, or even fax
you a copy if needed.

Good luck.

Hello Owen:
You may want to check out National Semi's web site at
www.national.com. They have an app note number 146, that talks about a
remote speaker system modulating at up to 20khz with a carrier of up
to 200khz over AC house wiring. It basically uses a modulated VCO for
the FM xmitter, and a PLL to lock onto the carrier and directly
demodulate FM at the receiver, and they claim pretty good specs. It
just might be the ticket to low frequency modulation for your
application.

The appnote is dated 1975! Sometimes the old stuff is better than the
newfangled expensive stuff, I have found!

Hope this helps.

831. Re: Bandwidth of a 14.4 modem?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-30 00:00:00 UTC
From: akent@bga.com
Message-ID: <505fnf$fpe@news3.realtime.net>
Source record: 102811

Hello:
If I remember right, most data modems over the phone lines use 2400hz
as the bandwidth. The modulation technique allows the higher data
rates (phasing techniques, etc.). Some of the newer phone systems
allow a higher bandwidth, but not all.

BTW: I am currently sending 115kb over SSB!!!!! (Weird modulation
techniques, and other tricks.)

Gary:

I have to agree with you wholeheartedly, in your discussion!

I currently have a prototype SSB radio modem operating at 115kb. It
blasts data. It doesn't support voice, though.

Of course, Ramsey is *infamous* for the extraordinarily poor filtering
on their receivers and transmitters. Several magazine articles in the
past 2 years have found that the transmitters were so dirty that they
were in violation of FCC regs. I was once young and naive enough to
buy one of their receiver kits. It was the first and last purchase I
ever made from them. Why? Well, a 20M CW receiver that has a bandpass
of about 25khz is pretty useless. :-)

>
Forget it. 2500W at 12V will require an input current of 210A. That
is a lot of current. It is not impossible, but quite a demanding task
and potentially dangerous. You would be much better off starting from
a much higher voltage. There was an article in RadCom about modifying
a car alternator to produce a.c by removing the diodes and adding
a new exciter/regulator circuit, but only to a few hundered watts.
A better prospect is a generator, or a stack of 12V lead acid batteries
in series giving maybe 48V or 120V d.c and an invertor kit. You can buy
these ready made reasonably cheaply.

837. The CW Question again?????????

Every day I download fifteen to twenty messages about CW (both pro & con) and I have one question for everyone: What does this have to do with Homebrewing?

None!

This is AMATEUR RADIO, a hobby not a job. The license is not required for employment. It is for enjoyment. Remember??? As for the CW requirement- let it stay, for those that don't like it- go over to 11 Meters. As for all of the other modes(Rtty, FSTV, SSTV, Satellite, Spread Spectrum, Clover, etc.) lets get those questions on the tests. The written tests as they are now, have become nothing more that a test of memorization and a joke. A parrot can regurgitate answers too.

There is not a strict relationship between bandwidrth and data rate.
However the signal to noise ratio on the channel will decrease as the
data rate increases for a fixed bandwidth. Eventually a practical
linit will be reached, depending on the channel signal strength and
noise.

I saw a version of this paper in RF Design.

In general, turning a Class C or D amplifier into a linear amplifier isn't worth it - you'll have to derate the output transistors to allow for the standing current on them, beef up the heatsinks to allow for the extra dissipation, and hope for the best when it comes to linearity. Transistors designed for high power switching amplifiers are designed to switch quickly with low on resistance. Linearity is just not a design requirement.

A reasonably accessible reference for this is Norm Dye and Helge Granberg's book on RF transistors (whose title escapes me at the moment...).

Get ahold of the HP Communications Components catalog. The
HSCH-9101 GaAs Beam Lead Schottky Barrier Diode is rated for
use through 44GHz and I'd be surprised if you couldn't get
it to give some useable rectification well above that. They
are kinda small and might be a challenge for the typical
experimenter to actually use. I have no idea what they cost.

>
>IMHO ones respect for a priviledge is proportional to the work required
>to obtain it.

I say that the worth of a privilege lies in what it enables a person
to do, today and tommorrow, not in what a person once did. Dusty trophies
are valued for what effort was once expended to gather them, but that effort
is remembered with as much pride (or lack thereof) even if the trophy is
hocked or stolen. No so with a license, its value lies solely in what can
be done with it, today and tommorrow.

It is a tool, not a trophy, and good tools are only of value in so far
as they enable one to do something of value. It matters not if the tool
were gained by great effort or merely found along the roadside. Its value
lies in what it enables one to do with it, today and tommorrow.

A craftsman takes care of his tools, because they enable him to accomplish
his tasks. Only a shallow collector (a fool with no real skills or talents
of his own) values his tools for what they once cost instead of for what
they allow him to accomplish, today and tommorrow.

Many of my most prized tools were inherited from my father. They are
without price as far as I'm concerned, though I did nothing to earn
them except by accident of birth. But my very most favorite ratchet
was found alongside the highway. It cost nothing, it has no sentimental
history, but holds a place of pride in my toolbox, and is the first tool
I reach for when a nut needs to be removed. I don't care what these tools
once cost, but I care very much what they allow me to do. I keep them
cleaned and oiled and carefully avoid abusing them in use, not because I'm
a collector, but because I am a craftsman and they are my life's blood
for accomplishing my tasks.

I view my amateur license the same way. What it cost to obtain is
yesterday's news, only fit to line bird cages. What it allows me to
do today and tommorrow is without price.

Gary

With perhaps the widest distribution of any amateur radio "magazine" in the world, www.hamradio-online.com is now being read in 43 countries around the globe. And its free, self supported by us and you, our readers who contribute great feature stories for this online magazine.

If you haven't paid us a visit, please stop on by and have a look around. There's lots to see - from feature stories all the time, to real-time propagation conditions, auroral conditions, meteor scatter info, disaster situation reports, newsletters from amateur organizations throughout the world, and our vast library of nearly a year's worth of online articles. And we allow reprinting of almost everything in club newsletters and other non-commercial publications and web sites (please see our reprint policy, online).

And watch for more cool stories and new features over the coming months. We already have a great line up of stories for September and October - and we plan to add some neat Java-based features as well.

Any recommendation would be suspect without the advisor knowing more
about your setup.

1. Does your receiver have a 50 ohm or Hi-Z input?
2. What type of antenna and feedline are you using?
3. Are you adept at building electronics equipment?
4. How much are you willing to spend for a tuner?

Instead of NPO capacitors, try capacitors with large negative temperature coefficients (N1500, etc...N1500 means -1500 PPM per degree C). I'll bet that the frequency of your oscillator drops when the temperature increases and a negative temp-co capacitor will push it in the correct direction. This temperature coefficient will be largely linear and a properly chosen capacitor will greatly improve the stability. If you are using a varicap diode for modulation, you could consider applying a correction voltage to it in addition to the audio. The process of finding the right value of temp-co capacitor or compensation voltage can be quite instructive! Another approach is to ovenize the whole circuit by placing it in a copper can with a proportional temperature controller. A simple controller is used in my water barometer in our technical library at www.wenzel.com. Let me know if you have any trouble finding parts including compensation capacitors or thermistors.

Source record: 102829

It was suggested to me that the RCA 833A was a poor tube choice for operation above 10 MHz, due to internal lead length and "tube structure". I guess that latter refers to interelectrode capacitance or possibly even transit time. Since the length of the lead from K to the input transformer will be on the order of 0.2% wave on 15 meters, I don't think that will be much of a problem. The plate lead will be shorter still and the grid lead shortest of all. Interelectrode capacitance is 12.3 pF for Cin and 8.5 pF Cout. These values are especially reasonable when you consider that the push-pull input circuit will place the capacitance of the two tubes in series while the parallel arrangement gives the sum of the tube Cinput. I don't think I'm gonna worry about the transit time.

True, while I write this in hundreds of small towns high school football games are being modulated and transmitted by 833A's in little Standard Broadcast stations. But for operation at 21 MHz they should compare favorably with the 4-400A or 3-500Z.

I thought distortion bore an inverse relationship to conduction angle and this is effectively 360 degrees in an class AB push-pull amp whereas the plate current is cut off during the negative peaks with a single-ended amplifier. So I think that I will have a reduction of of odd harmonics, but not as much as even order products.
Current sharing should be less of a problem...

But getting away from these Mason jars I intend to use and to the original question. Does anyone think that there is an increase in efficiency in the plate coil above 14 MHz with a plug-in coil design? I sense that there is an advantage in not having the turns that are used for 160 to 40 doing who knows what on the upper bands. Anyone have any thoughts on this?

I thank all for the knowledge shared here and urge you get in your shack and build something. You can build better and cheaper than you can buy if you just do a little research and a lot of scrounging and planning.

Why don't you build your own? Check out the copper wire table in the ARRL manual. Choose a suitable gauge of wire and cut the appropriate length. If inductance is not a problem you could wind it on a coil form. Or how about paralleling some 0.1 ohm or 0.5 ohm resistors, both common values. I've successfully made amp meter shunts using the wire table as a guide.

Hi Tovar,

First of all, good to see someone with the guts to keep at the CW when there's a real difficulty to get around; I salute you and wish you luck!

I know what you mean about the money situation; my business recently took a hammering and so I'm now trying to get back on the air on a shoestring; fortunately some years ago I'd boughtn some test gear. Do you ever visit shows or local rallies? Over here in the UK you can pick up bits of functional older test gear. Also, any club will have people who can help with access to test equipment.

Get involved in a local club and see if you can organise 'Testing Nights' where club members with the kit and expertise could help other members test their homebrew stuff? In return, you could provide 'digital technology' sessions where you give information out on your specialist areas?

Just a few thoughts

>your brains on this one.

>Thanks.

Hi,

A multiplier approach needn't be too horrible; I've set tem up with a
dip meter and a scope and I would have thought that a couple of stages
would be adequate.

As to an LC set up with maximum stability, the main things to remember
are:
Get a good VHF transistor.
Isolate the oscillator from theaerial by a single stage buffer and
minimise aerial loading.
Stable power supply; watch using Zeners as the capacitance can
sometimes impact on the oscillator unless it's isolated by a choke
from the oscillator surcuit.
Consider etching the inductance on a PC board?
Use varicap tuning rather than a VC?

Hope this helps

860. Low TCR variable resistor for RF application?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-08-31 00:00:00 UTC
From: nickel@widget.ecn.purdue.edu
Message-ID: <509ndj$cio@mozo.cc.purdue.edu>
Source record: 102744

I'm working on a project that uses a Wheatstone bridge to measure the really fast fluctuations from a resistance-based sensor (the whole fluctuation lasts a few microseconds, and we'd like to see sub-microsecond events during the interval). I make various sensors with different nominal resistances, so I'd like to use a variable compensating resistor that I can "tune in" to balance the bridge.

The relative resistance change from the sensor is small (1000's of ppm full scale), so I would like a stable compensating resistor -- thermal drift is annoying, mechanical noise is deadly.

What kind of variable resistor could I use to select a value from 100 to 1000 Ohms, tunable to about 1 Ohm, stable to 0.1 milliOhm, that's mostly a resistor at 10 MHz?

Thanks for any suggestions,
Dave Nickel

Coincidentally, we have a very similar requirement here at HP
for the same thing. BTW, in addition to your requirements, we
need low reactance; I don't know if that applies to you as well.
Of course, a PIN diode comes to mind. Since both of us only
need to change a fraction of a %, one thing that comes to mind
is to put matched PIN diodes in both legs of the bridge, and
vary them differentially (or just hold one constant). The drift
should cancel pretty well as long as you run substantially the
same current in each.

If anyone else has any thoughts on this, I would greatly
appreciate hearing about them.

The wire wouldn't stand the current.

The power supply is rated at 35 amp intermittent/30 amp
continuous. 35/4= about 9 amps. The voltage drop would be about
9 * .05 or .45 volt. The wattage would be .45 * 9 or about 4 watts.

That's assuming that the current is equally distributed.

Note also that I received a number of responses that indicated that
others have replaced the resistors. The resistors also act as fuses.

There is some extra room but a 5w 5% resistor is a pretty small package.
Winding number 10 wire won't make it, hi hi.

Nichrome wire would not have a stable resistance between 0 and 9 amps.

>amongst radio amateur home brewers. We're looking for a solid state
>portable unit. Can anyone recommend a manufacturer of a low cost unit
>(the Heath company used to offer such a unit, as well as Eico and many
>others), or even offer a used unit? Delivery is for israel.

MFJ makes an "SWR Analyzer" which covers about 1.5-170MHz with digital readouts (they also have a couple of cheaper calibrated-dial units) that measures SWR and also antenna impedance on their higher end model. They also sale an add-on kit for a "grid-dip" which basically consists of a couple of coils and a nice little book. The SWR analyzer sales for approxamatly $200 for the high end and the grid-dip attachment costs somewhere around $30 if I remember right. I bought my grid-dip kit for $5 at a hamfest and I saw an analyzer for about $140 used at a 'fest last month.

Other choices would be the ARRL handbook. It seems like they have at least one schematic of grid-dip meters in there.

Good luck

I'm looking to an original solution for a VHF Repeater.
In France we use a 600Khz Shift and most of the repeater use cavities. I've heard that it was possible to use a more recent solution with microprocessors : By reinjecting the tx signal in the receiver but in phase opposition...
Does anyone have informations about this technic, is it possible to find description of such realizations?

Marty,

Try the ARRL Spread Spectrum Sourcebook, there is some info on home brewing.

What band are you building in and what are you using it for (data or voice)?
Many IC manufactures (Harris, Motorola, etc) are just coming out with chip
sets for SS. All of these chip sets are for data transmission in the 902 or
2.4 Ghz band but you could up or down convert to the RF band of your choice.
Harris has a site on the WWW...

Have fun, keep up the home brewing!

Try using an overtone crystal oscillator circuit. They oscillate directly on the desired frequency without any multiplication, using just a single transistor. Information can be found in any ARRL handbook.

Good idea in that no multipliers are needed, but be sure you can swing
the xtal osc far enough to generate the wideband FM needed.

Hi Ian,

Thanks for your response. All is noted.

However I am a bit of a scrounger (always looking for junk to use)
so I bet I will eventually find something????

A company here in Australia has a NTSC>PAL converter for $AUS89,
not a bad price, well within my cost budjet, however as you pointed out
the point of my origional posting was to look at a homebrew method and
apparently, this is either not available or cost prohibitive.

none the less, thanks again to you, and all those others that responded
(also sent Cc to ham-homebrew).

73 till next time

I don't recall a magazine article, but I remember FS meter articles in some
of the older handbooks I've got. Unfortunately, all my radio stuff is still
in boxes, as I've just moved from NJ to OH.

If no one else comes up with the article, send me a note. I should have
dug myself out from this mess within the next week or so.

I don't know about web pages on the subject, but you might do this for
a start:

- Begin with kits. QST seems to have more companies offering kits than
I've seen in a long time. If you don't want mail/phone order, check out
the Ramsey kits available at Radio Shack. They're a mixed bag when it
comes to quality, but you won't go broke doing it.

- Begin collecting catalogs. Sometimes, one of the hardest things about
homebrewing can be finding the right parts.

- Pick up "Hints and Kinks" and other books on tricks of construction.

- Choose a simple project or two from a magazine or handbook and try it.
Learn by doing.

- As you read articles etc., note which components keep popping up over
and over. You'll find that certain ICs, transistors, etc. are much
more popular (at least among Hams), and reducing the jillion options
you'll find in catalogs down to a few very useful options will make
learning easier.

And then, as Cole Porter said: "Experiment!" (Yes, Cole Porter.)

All AM Brodcast transmitters built today use MOSFETs. As to low power

I guess 1000 Kw is still considered low power ?

>Less power and more antenna gain results in the same radiated
>signal strength, but as frequency increases, path loss increases the
>same amount that antenna gain increases (all other factors
>being held constant, including coax loss). So the *same*
>power is required.

Not quite. The misnamed "path" loss contains two factors, both
geometric. The first "loss" is the good old inverse square decline
in power density with increasing distance. This is the same at every
frequency and is merely the geometric consequence of the expanding
wavefront.

The second "loss" is the capture area of the receiving antenna.
For an antenna of constant *electrical* size, "loss" increases with
increasing frequency. The cause of this is also geometric. The physical
area of the antenna declines with increasing frequency (declining
wavelength) for a constant electrical size. Thus the number of square
meters of the signal wavefront it intercepts declines, and the amount
of signal power it captures declines.

But if you keep the antenna a constant *physical* size, the capture
area does not decline with frequency, and the "path" loss does not
increase with frequency.

Both of these "loss" terms implicitly assume an isotropic source.
If the source is not isotropic, but is instead another physical
antenna matching the receiving antenna, things get more interesting.
Now transmit antenna *gain* must be included in the calculation.
This is another geometric effect, modifying the isotropic source
wavefront intensity in one direction at the expense of energy in
other directions. If that direction happens to be that of the
receiving antenna, the square meters over which the receive antenna

captures signal will each have a higher power density, and more signal will be recovered.

So for a pair of antennas of constant *physical* size, "path" loss *declines* with increasing frequency.

As you can see, the "path" really has nothing to do with it. The "path" loss is there in vacuum where there is nothing to attenuate the signal because the "path" loss is really just an artifact of geometry.

Now there can be *real* path losses we have to consider. If the path is not through vacuum, but is through some other medium which *is* lossy, then we can have real path losses. This can be frequency dependent. For example, at microwave there are certain frequencies which are readily absorbed by water vapor. This is *real* path loss because the energy of the wavefront is absorbed and dissipated heating water.

There are also scattering "losses" to be considered. While this is more geometry, the loss is real in the sense the RF energy doesn't wind up in the vicinity of the receiving antenna. At certain frequencies, RF energy is scattered off the molecules in the air. This changes their direction and reduces the amount of energy passing along the straight ray path to the receiving antenna. (But we can use this to our advantage over an obstructed path by using the scattered energy as our signal path. This is called forward scatter propagation.)

Ignoring these two real losses, which are only significant at certain microwave frequencies, however, we see that geometry insists that there is really less "path" loss as we go up in frequency if we keep the transmit and receive antennas a constant *physical* size.

Ah, but what kind of radio do we want to build? Old digital or
new digital? And should we build our old digital radios with
new digital parts or build our new digital radios with old fashioned
analog parts? Decisions, decisions. :-)

Point taken, however, and I'll try to point follow-ups to more
appropriate groups. Please excuse if some of the massive cross
posts go astray from time to time.

That'll work, but you'll get a headache in a hurry from the 10 Hz
flicker caused by the difference in field rates. There are two
ways to cure that. One is to use a CRT with a long persistence
phosphor, but that'll give you trailing on moving objects. Or
you can use a mechanical shutter slaved to a multiple of the
field rate. It should show 360 frames/sec for NTSC. That'll
push the flicker frequency too high for you to notice. We used
to do this with a wheel having a *bunch* of holes in it, spun
with a synchronous motor. Today you might try using a transmission
LCD in front of the camera pickup pulsed by a mulitiple of the
field rate.

>
>True ... However, it's not likely to work over a SSB radio channel
><grin>.

It can, if you nail up a duplex radio link and let the modems
train. You have to duplicate the conditions under which the
modem is designed to operate in order for it to operate properly.
In ye olden days, international telephone links were via pairs of
HF SSB radio channels. Unless you have a SNR of 40 db or better
though, your BER will be high and the modems are likely to keep
dropping into another training sequence.

Now OTOH, I have some 900 MHz duplex radios which are intended
to emulate a Bell standard phone line, and they work just ducky
over an unobstructed path. Even 28.8 kbps modems work fine over
their 3 kHz baseband.

For half-duplex links where the modems can't train, you've
got problems. You have to blow out the bandwidth to make up
for the lack of dynamic equalization, IE fewer bits per baud,
so you don't get much throughput at all in a 3 kHz channel.
If you fall back to MSK, you can get about 1.4 Hz/baud, or
a bandwidth of 20.16 kHz for a 14.4 kb data stream.

If in addition the channel is fading, things get really tough.
You have to add FEC and maybe ARQ to deal with it. FEC eats
bandwidth just as if it were data, so your throughput suffers.

>are a marketer's dream.

While there are certainly people like you describe who are only chasing status symbols, in fairness there are those who are fascinated with the cutting edge, who want to know all about the latest techniques, every bit and baud, who want to experience the best performance possible. These are people to whom the words "Hilbert Transform", "trellis coding", and "Reed-Solomon" come as easily as the words "straight key" come to you. When they talk about Shannon, they don't mean Del, or the Runaways.

There's a name for this sort of person, it is First Adopter. There's another word which better describes this sort of person, it is *pioneer*. The first amateurs to switch from spark to CW, from AM to SSB, from Morse to Baudot, from RTTY to PACTOR were the same breed. To them, the direst enemy of "better" is "good enough". Their status is never quo. Don't make fun of them, they are the drivers of progress. The rest of us will trail along behind them, following the trail they have broken for us, as time marches on and the formerly exotic becomes the commonplace.

At every step along the road, there will be those left behind. Those who will say "spark is good enough", or "CW is good enough" or "AM is good enough" or "RTTY is good enough". But if they tarry too long, they may find themselves *hopelessly* left behind and unable to catch up with everyone else, or even comprehend what everyone else is doing. They will become alienated from the mainstream, forced to live in yesterday's paradigm, forever, alone.

Like modern day Luddites, they may strike out in a blind rage against
the new ways, or they may find their niche, a sort of radio Amish, where
they can rest content to let the rest of the world speed ahead while
they remain true to old Dobbin and the buggy he pulls. The latter we
can tolerate, even respect, but the former we must fight at every turn
or they'll bring us all down to their spiritually impoverished level.
We can soar with the eagles, or meekly let our wings be clipped and
be forced to grub along on the ground by those jealous of the heights
we have reached.

Gee, I feel like unfurling a banner and shouting "Excelsior!"
Am I alone in being an unabashed cheerleader for progress?
Should we all be hobbled to VT2s and Brass Racers forever?
Or is it past time to move on?

>
>First off, what about a schematic and/or kit for a 6 meter radio?

Well, most of the excitement on 6m is on SSB. There is activity using FM, and there are repeaters, but that's much like 2m. Most of the Dxing is via SSB, or via one of the modern digital modes, or via CW. The traditional route is to use a transverter to convert up from a HF rig, or if you don't have a HF rig, then transvert down from a 2m multimode. Since a transverter is just LO, mixer, and amplifier, this is usually the simplest route.

The RSGB's VHF DX Book has good transverter circuits.

Now if you don't have a HF rig or a 2m multimode, an old SSB CB set will do. You can either use it to drive a transverter, or convert it to work directly on 6m (probably the better way to go). You can scratch build, but its a bit easier to have a working exciter as a starting point. If you do want to build it all, then the R2 and T2 kits can let you do that with minimum complexity. Providing the on channel VFO is the hardest part of this approach.

73 Magazine had an article on converting a SSB CB to 6m a few years ago. The T2 and R2 kits were described by Rick Campbell in QST. The kits are available from Kanga Products.

Of course if FM will satisfy you, this is trivial to build. There are single IC FM transmitters and single IC FM receivers available. You can get them from Motorola, or scavenge them out of an old cordless phone (they operate on 49 MHz, and it is trivial to move them onto 6m). You'll need to add a power amp to boost the signal up to useful levels.

Motorola has application notes.

Another way to go is a Ramsey kit, but I don't recomend that. It looks like a ham rig, but it doesn't work very well.

>And secondly, what about a schematic and/or kit for a RADAR Gun? I am
>assuming this one is legal of course. Correct me if I'm wrong here! Was
>wanting to build a RADAR gun and clock vehicles,check speeds,etc.

Ramsey offers a kit. It's junk. This is a project where scrounging will really pay off. What you want is the motion detector gunnplexer out of an automatic door opener or alarm system. This has a gunn oscillator in a waveguide cavity and a detector diode. Now all you need to add is a power supply and an audio amplifier and audio frequency counter. The pitch of the audio tone will be directly proportional to the doppler of the moving object. If you use a simple frequency counter with an analog meter movement, use a frequency to voltage IC available at Radio Shack, you can calibrate the meter scale to read out directly in MPH. Add a horm antenna made out of sheetmetal to the waveguide to increase range.

The two volume RSGB Microwave handbook has all you'll ever want to know about gunnplexers and horn antennas. 73 Magazine also had a project for building a speed gun based on a gunnplexer a few years ago. Find a library, or a ham, with a collection of 73.

889. Morse training programs?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-01 00:00:00 UTC
From: mista.moron@mail.link.no
Message-ID: <50dn8q$9qp@lex.zippo.com>
Source record: 102769

I'm considering to get a ham licence, and since this here in No-way means that I have to learn morse, I was wondering if there is any morse training programs for DOS/Windows 3.1 available, preferably PD/shareware.
I also wonder if there is possible to get some kind of automatic morse decoding programs, so I could connect the receiver (and maybe also a transmitter) to the computer (ie. via the soundcard or a simple home-made interface) so I could receive (and maybe also xmit) morse as text on the screen.

Apparently FMing an overtone oscillator through the necessary range
(+/- 75 kHz) is pretty tricky. Don Lancaster did have one example
in his column in Radio-Electronics or Electronics Now magazine several
years back. He reverse engineered the schematic out of one of those
car radio - CD adaptors that Panasonic or Sony sell. Something about
using a tuned cicuit at resonance to magnify the varying reactance, so
instead of just a varying capacitance, it would go both capacitive and
inductive.

I think it was maybe 5 years back, try www.tinaja.com, his web site
to see if he has a reprint on file.

it can be done, I for for one would believe him. Larry, WB6VGI.

893. Need VOX for KWood TS-50/60?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-01 00:00:00 UTC
From: Larry Minnis <wb6vgi@erols.com>
Message-ID: <322A342D.6692@erols.com>
Source record: 102773
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I have a Kenwood TS-50 that I haul down to Gitmo, Cuba all the time. I love the rig but have been trying to figure out how to come up with VOX for it. I have a Heil boom set that I use so I can type on the laptop as I talk. The footswitch works, but "walks" around the floor. Well, I've finally found the solution. The ICOM EX-1514 external VOX unit! After getting the schematic from ICOM, a bit research revealed that only minor modifications would be required. This modification requires a rewire of the mike plug on the front of the unit. After carefully checking the pinouts vs wire color, I rewired the mike jack on the unit for a Kenwood radio. Rather than changing attached mike plug and playing with the mike jack on the EX-1514, its easier to just pull all the wires off of the mike jack. I then rewired the jack to look like a Kenwood mike jack. I attached the wires from the vox unit to the mike wires with some small shrink tubing before soldering back to the jack. This keeps you from having to fight with two wires on the same pin on the back of the jack. The VOX unit pulls the required power off of the TS-50/60 mike pin along with the audio needed for the anti-vox circuit. Works great and only minor amount of work with a soldering iron. I'll be testing it out on my next trip to KG4 land starting on the 10th of September. Hope to work you from there. Larry, WB6VGI/KG4ML.

A device used at the airport to detect weapons?

I disagree with Douglas J. Mar (mar@zoltar.nrl.navy.mil) below. If you plot the voltage across a tunnel diode against the current through it, there is a area where the slope is negative. That is: take two points one described by I1 at V1 and the other by I2 at V2 and solve for resistance using the equation R = (V1-V2)/(I1-I2). The result is negative. This equation will always produce a positive result for conventional resistors. This is not nit picking or playing at semantics - it's a matter of mathamatical definition.

It is also required that the resistance be negative from the following line of reasoning: A normal resistor can only disipate power - it can only produce a loss. No way to get gain out of a resistor. Just as a positive resistance produces loss, a negative resistance produces gain. (That's how the circuits he mentions work. It's just that a tunnel diode does the same thing in a simple two terminal device.) Tunnel diodes produce gain. They can be used as amplifiers. They can also be used in oscillator circuits. To oscilate, a circuit must have at least enough gain to overcome its losses. Since no real circuit can be lossless, and oscilator must contain a gain element.

I think a way to include his point is to realize that all active circuits consume more power than they produce as output. They have less than 100% effiency. (Otherwise we would have perperual motion machines.) The diode consumes real positive power a part of which is disipated in internal (positive) resistance loss and part is turned into output by a negative resistance.

Now, what's a gun diode? Don't know beyond Doug's comment that it's an active device used at microwave frequencies. Gunn is the name of its inventor. Now aren't you sorry you asked?

Subject: Re: HELP: IS PC SWITCHING POWER SUPPLY OK???
Organization: Just my little old self

No problem with switchers per se, but pirateing a computer supply is
not without its problems.

All switchers require a minimum load. In many computer supplies its
the fan. Some assume some minimum load on the mother board. They go
out of regulation or stop oscillating and smoke with less than the
minimum current draw.

My ICOM IC740 has the optional built-in 13.8 volt supply and it works
fine but it was designed for communications.

There is a big difference between 12 volts and 13.8 volts. In the
case of my Radio Shack HTX-202 2 meter handy-talky it's 6 Watts at
13.8 and 5 W at 12.0. That's a 20% drop in power. Most mobile
equipment assumes a vehicle with a running alternator which is where
the 13.8 value comes from.

>Tovar <tvr@alive.com> wrote:
>
>>So what are my options? Is there much that one can do in the RF realm
>>without a lot of money or learning CW first?

Pardon me for following up Joe's message, but the original didn't make it here. Let me address what one can do without learning CW first. In a short sentence, the answer is "anything you wish outside of HF." Current regulations limit you to only receiver, accessory, and antenna projects for HF if you don't pass a Morse test, IE no transmitting. While those things are interesting in and of themselves, they're more SWL than amateur radio. Above 30 MHz, however, the whole world of amateur radio is open to you.

With little money and little or no test equipment, the easiest projects revolve around FM equipment. The receivers are easy because they run wide open hard limiting. So they are easier to tame and tune up than SSB/CW receivers. And most of the guts are available as a chip or two. FM transmitters are similarly easy, just a carrier source with a varactor across the oscillator fed by a mic preamp. Simple, almost foolproof. For both FM receivers and FM transmitters, your ears are the most important piece of test equipment. You tune them until they sound good. Simple.

Of course there is more to it than that if you're shooting for high performance, but you can certainly build equipment adequate for local use with little in the way of tools and test equipment. Even for high performance, a pulsed noise source is easy to build, and about as useful as a $20,000 network analyser for tuning up a preamp. You don't have to memorize an arcane coding either, plain language English will do.

At 70cm and above, it gets even simpler. Most designs can use printed lines for the tuned circuits. These "no tune" radios are almost foolproof. Solder on the MMICs and DBMs and start operating.

At microwave, your primary tools are saws, files, and very finely marked rulers. For most projects, exotic test equipment isn't needed. You can have a 10 GHz station on the air in an hour if you happen to have a utility audio amplifier lying around. It'll be useful up to 1/4 to 1/2 mile. You can have an even better station if you happen to have an old portable broadcast FM receiver lying around. That'll give you enough gain and

selectivity to work 10s of miles over the right terrain using
the gunnplexer and a simple dish made from an ordinary snow
coaster, a big kitchen pot lid can be made to work too.

Homebrew gets *easier* as you go up in frequency. Since low
power is plenty for line of sight, costs are low too. HF
circuits are a pain in the butt to work with, save them
until you have more experience. Get up where the waves
are ultrashort and the building is easy. And remember
that with FM there is no static at all.

Gary

All you need for Digital Amateur communications.

Does RTTY, CW, FAX, SSTV up to 16 million colors

Monitor packit without the cost of a modem.

Join the 14.230 and 14.233 SSTV Nets.
2 meter SSTV getting hotter every day, don't be left out.

Copy CW up to 40 wpm.(catch all the ARRL buletins)

look in on Ship to shore SYNOP, NAVTEX, etc.

Get weather faxes with your two meter rig.

(((All for $17.00 +SH!)))

Over 100 in stock.

Send a check and you will be on the air in less than a week.
I ship the same day, I receive your check.

Take a look at http://www.cris.com/~n9zle/hc.html
mailto:n9zle@concentric.net
I will also be at the Louisville Hamfest Sept 7-8

Not by using micros, but isn't this sort of like how the rat-race or ring
duplexers work? What about the noise (uncorrelated)? Brute force
filtering is still required, me thinks.

A digital solution to an analog problem is never a good idea. (Any Bob
Pease, Pease's Porrige, fans out there?)

Hi Hipiket,

In article <508a7g$ion@newsbf02.news.aol.com>, hipiket@aol.com (Hipiket) writes:

>It was suggested to me that the RCA 833A was a poor tube choice for
>operation above 10 MHz, due to internal lead length and "tube structure".
>I guess that latter refers to interelectrode capacitance or possibly even
>transit time.

It's a problem of self-resonance in the internal structure. The grid capacitance, along with inductance from the long grid structure and single grid lead, lowers the self neutralizing frquency of the tube. This makes the tube unstable at lower frequencies.

Examples of this can be found by looking at the parasitic suppression methods required to stabilize various tubes. Tubes with long single grid leads and large grids like the 811 or 572 require large suppressor inductance, while tubes with compact grids (ie 8877) and coaxial grid connections often don't require any suppression at all.

The 833 is the granddaddy of low self-neutralizing frequencies, so stabilizing the tube without overdissipating the suppressor is a chore. That isn't to say it can't be done (I've made sweep tubes work on 6 meters and higher), just that you should be prepared for difficulties above 14 MHz.

>games are being modulated and transmitted by 833A's in little Standard
>Broadcast stations. But for operation at 21 MHz they should compare
>favorably with the 4-400A or 3-500Z.

The self neutralizing frequency of a 3-500Z is just under 100 MHz, with a 833A it's around 20 MHz. Imagine using a 3-500Z at 144 MHz. That's what you're up against with a 833A on 28 MHz. You'll find all sorts of regeneration because the anode to cathode feedthrough capacitance will become very high above 7 MHz.

>I thought distortion bore an inverse relationship to conduction angle and
>this is effectively 360 degrees in an class AB push-pull amp whereas the
>plate current is cut off during the negative peaks with a single-ended
>amplifier.

Don't confuse distortion of the RF sine wave with IM distortion of a two tone signal. Distortion of the RF sine wave is indeed less in a push pull RF amplifier, and directly related to conduction angle. Reduced even order harmonics of the driving frequency are the result of reduced RF sine wave

distortion.

On the other hand, IM products are directly related to gain linearity as drive level is varied. Once a power grid tube is biased in conduction at zero drive, very little change in IMD performance occurs with larger conduction angles. Operating an RF amplifier in push-pull does not, as a general rule, change IMD performance a great amount unless regeneration is reduced.

>Current sharing should be less of a problem...

It will be just as much a problem. If one tube is operated in a non-linear portion of its gain curve, it will contribute exactly the same distortion in push pull as it would in parallel. Tube to tube balance will greatly affect harmonic suppression. Remember IMD is caused by non-linearity as the driving signal is varied in amplitude, NOT by non-symetrical reproduction of the RF sine wave. It is possible to have VERY good IMD performance in a single ended PA, in excess of -40dB, even though the conduction angle is just barely over 180 degrees.

If conducton angle was reduced to 120 degrees *per tube* at full drive, and two tubes were used in push pull, IMD would be horrible. It would be little or no better than a single ended amp operated at 120 degree conduction angle. That's because at a certain level of drive, the tube simply quits amplifying. It's not only flat-topping that causes IMD, it's low level clipping. Solid state exciters are good at this, they often have POORER IMD performance at low power levels than at high power levels. If low level non-linearity is a problem, reducing drive levels won't reduce splatter...it will actually make it WORSE as a percentage of peak power. That's one of the reasons asking someone with a NASTY amplifier to "turn it down" sometimes does no good at all.

This is one of the reasons authors should be called to task for suggesting people built tetrode amplifiers that can be driven with ten or twenty watts. The idea of a ten watt drive PA being used with a 100 watt rig is ***stupid*** (in the most polite term).

>But getting away from these Mason jars I intend to use and to the
original
>question. Does anyone think that there is an increase in efficiency in
the
>plate coil above 14 MHz with a plug-in coil design? I sense that there is
>an advantage in not having the turns that are used for 160 to 40 doing
who
>knows what on the upper bands. Anyone have any thoughts on this?

A typical amateur grade multi-band tank circuit only consumes a few percent of the total RF power. By far the largest concentration of loss is in the PA tube. If all tank loss was eliminated, there would be only a few percent improvement. The tube type, and even waveforms in the cathode circuit, affect efficiency much more than eliminating a few shorted turns in the tank.

I had a *crystal* radio built from a kit when I was a kid. It too was a boy scout project. The detector was a metal cup about 1/2" deep and also 1/2" diameter. The cup was filled with solder and in the middle of the solder, with a surface sticking above, was a galina (spelling) crystal. It worked great.

Some thoughts. Mine and the razor blade version differ in the detector used. It was much like the razor blade version. Steel is iron with some carbon in it and there are spots where the alloying is not perfect and some carbon crystals exist. This is what you're hunting for when you probe around to find a *sweet spot*. The wire probe is the *cats whisker*. I'm guessing my whisker was phosphore/bronze from its color and springyness. Since it's the other half of the diode, experiment with different materials.

Mine had some added features that will improve the radio described below by Craig (AA0ZZ). If you have more than one strong station you may get them all together. An LC tuning between the antenna and the detector will give a good deal of selectivity. Mine had a coil reminisent of a toilet paper tube wrapped with 3 or 4 inches of maybe #30 enameled wire. A fixed capacitor was in parallel with the coil and a sliding wiper shorted out part of the coil to produce a variable LC. One end of the tuned circuit went to ground the other to the antenna. The antenna also went to the detector. The other side of the detector went to the headphones which returned to ground. Got good volume and good selectivity with a 50 foot overhead wire at my home about 30 miles from the Philadelphia radio stations. It was great fun.

My father told me before tube radios became affordable a good crystal set with the earphone carefully placed in a crystal glass bowl (a punch bowl) gave something loud enough for family entertainment. The crystal glass resonated - don't know if a modern plastic one would work. The other trick was to put the earphone at the small end of the *morning glory* horn found on old acoustic record players. This easily gave room volume.

Good luck

No problem with switchers per se, but pirateing a computer supply is
not without its problems.

All switchers require a minimum load. In many computer supplies its
the fan. Some assume some minimum load on the mother board. They go
out of regulation or stop oscillating and smoke with less than the
minimum current draw.

My ICOM IC740 has the optional built-in 13.8 volt supply and it works
fine but it was designed for communications.

There is a big difference between 12 volts and 13.8 volts. In the
case of my Radio Shack HTX-202 2 meter handy-talky it's 6 Watts at
13.8 and 5 W at 12.0. That's a 20% drop in power. Most mobile
equipment assumes a vehicle with a running alternator which is where
the 13.8 value comes from.

A device used at the airport to detect weapons?

I disagree with Douglas J. Mar (mar@zoltar.nrl.navy.mil) below. If you plot the voltage across a tunnel diode against the current through it, there is a area where the slope is negative. That is: take two points one described by I1 at V1 and the other by I2 at V2 and solve for resistance using the equation R = (V1-V2)/(I1-I2). The result is negative. This equation will always produce a positive result for conventional resistors. This is not nit picking or playing at semantics - it's a matter of mathamatical definition.

It is also required that the resistance be negative from the following line of reasoning: A normal resistor can only disipate power - it can only produce a loss. No way to get gain out of a resistor. Just as a positive resistance produces loss, a negative resistance produces gain. (That's how the circuits he mentions work. It's just that a tunnel diode does the same thing in a simple two terminal device.) Tunnel diodes produce gain. They can be used as amplifiers. They can also be used in oscillator circuits. To oscilate, a circuit must have at least enough gain to overcome its losses. Since no real circuit can be lossless, and oscilator must contain a gain element.

I think a way to include his point is to realize that all active circuits consume more power than they produce as output. They have less than 100% effiency. (Otherwise we would have perperual motion machines.) The diode consumes real positive power a part of which is disipated in internal (positive) resistance loss and part is turned into output by a negative resistance.

Now, what's a gun diode? Don't know beyond Doug's comment that it's an active device used at microwave frequencies. Gunn is the name of its inventor. Now aren't you sorry you asked?

If low level non-linearity is a problem, reducing drive levels won't reduce splatter...it will actually make it WORSE as a percentage of peak power. That's one of the reasons asking someone with a NASTY amplifier to "turn it down" sometimes does no good at all.

This is one of the reasons authors should be called to task for suggesting people built tetrode amplifiers that can be driven with ten or twenty watts. The idea of a ten watt drive PA being used with a 100 watt rig is ***stupid*** (in the most polite term).

>But getting away from these Mason jars I intend to use and to the

who
>knows what on the upper bands. Anyone have any thoughts on this?

A typical amateur grade multi-band tank circuit only consumes a few percent of the total RF power. By far the largest concentration of loss is in the PA tube. If all tank loss was eliminated, there would be only a few

percent improvement. The tube type, and even waveforms in the cathode circuit, affect efficiency much more than eliminating a few shorted turns in the tank.

Another good point to make about the ARRL ... even when they *think*
they're trying to be progressive, they're at least 5 years behind the
power curve of technology.

But they'll bill themselves as "fostering technological growth in the
amateur community". If it weren't so pathetic, it'd be funny.

Oh well ... the comment has been made that the folks at ARRL couldn't
make it anywhere else ... this illustrates why ... sort of like the old
adage "Those who can do, those who can't teach."

>the prospects. I will probably go with a VHF/UHF handheld on the first pass.

For my Icom W2A, I just bought a standard size speaker mike, took it apart, and mounted the bits in my helmet. I omitted the switch from this installation, of course, so if you just plug the helmet straight into the radio it will immediately xmit.

On the bike, I made a simple harness that plugs into the radio. The earphone circuit feeds straight through to a female mini-stereo in-line jack for the helmet connecter. The mic lead goes through a switch (a flat membrane switch velcroed to the switch housing on the left bar) and on to the helmet plug. The W2A uses a switched mic lead. If the radio sees the mic circuit connected it goes to xmit.

This circuit has worked very well for several years. Several times I have forgotten and exited the bike without unhooking. The stereo mini-plug/jack pulls apart very easily with no damage (a good reason not to panel-mount the jack).

Let me know how it goes...

Message-ID: <50ekju$sg3@erinews.ericsson.se>
Source record: 102779

Want to assemble a remote controlled RX site.
Looking for ideas on 'how to', that is - what
receivers, interfaces, computer programs, bits of HW, is
available and can be used together to form the remote RX.
Are there previous ham-mag. articles or sites to study?

The idea in general is to use an FM control channel to the
remote RX site, the 'users' need to have DTMF.
The remote RX audio should be availabel on FM audio channel.
No restriction is neccessary on users, although an 'access code'
to activiate the RX should be of interest.
Have ICOM R7 RX, but other RXs can be discussed.

>adage "Those who can do, those who can't teach."

That is not fair, Carl. Technical book publishing has a very long
lead time, unlike a penny dreadful true confessions ripoff. Facts
and details have to be extensively checked and confirmed several
times between the author's submission and the final plating. Printers
are notorious for screwing up equations and diagrams. Even authors
make mistakes that aren't caught until late in the process. It is
not unusual for a technical book to be in process for over a year.

(Remember too that the ARRL doesn't assign an editor full time to
a book, except the Handbook, so the editor is doing this in spare
moments between other tasks. And frankly the editor of this book
is spread so thin I don't know how he gets anything done. I respect
his competence, but I also know something about his working
conditions. If I were in his position, I'd quit. Most of the HQ
staff are competent people, but the Peter Principle is definitely
at work at HQ on the upper levels.)

The ARRL depends on amateur authors who write when and what
they feel like writing. They simply don't respond to the same
deadline pressures as professional writers. It may take a year
or more between the decision to do a book and the time the first
author's manuscript arrives on the editor's desk. Allowing for
the in process time, that means the book may take two years

between the time the decision is made to do it and the presses start rolling.

(*If* you have a competent professional writer, and *if* you have an editor who can devote sufficient time to the project, you *can* produce a better book in a shorter time. But that's not the case for ARRL publications in general. Though I must say that there are some gems in the ARRL library. A couple of the net citizens here have written some really nice books for the ARRL.)

Most technical books are behind the curve by the time they hit the book store, at least they are if they are about modern and rapidly evolving techniques such as spread spectrum. This one has been out for a while, so it is no surprise that it lags the SOTA.

That said, this particular book shows inconsistent style, and clear indications of padding. It is a compilation book with a lack of strong editorial direction, IE the editor had to use what he got (there were a number of places where I was screaming "Rewrite!" while I read it). It's pretty obvious that the editor didn't get all the material he wanted and had to pad it out with rehashes of FCC proceedings and the like. (IMHO a third of it could have been cut without losing anything important, though perhaps to someone who hadn't been following spread spectrum issues in amateur radio the background might prove informative.) Still, it is the *only* amateur radio book devoted to spread spectrum, and thus worth reading.

I felt that I got my money's worth out of it for just one circuit idea that I hadn't seen before anywhere else dealing with the clock synchronization problem. And for someone who knows zero about spread spectrum, the book can serve as an introduction (albeit a somewhat confused one due to the compilation nature of the book).

There are some professional level texts out there on spread spectrum, but most of them are dated too, and would daunt many amateurs due to the extensive use of Greek letters and complex equations and lack of concrete circuit examples. For someone with a bit of background in spread spectrum, the chip manufacturers app notes have the best information. But if you don't have the background, you won't understand what they're telling you.

I don't see what's unfair about "calling a spade a spade" ... if
you're going to publish stuff purporting to be up-to-date and covering
the latest technology, you should find a way to do it, or forget it,
rather than passing off "yesterday's news" as "what's hot for tomorrow."

>(*If* you have a competent professional writer, and *if* you
>have an editor who can devote sufficient time to the project,
>you *can* produce a better book in a shorter time. But that's
>not the case for ARRL publications in general.

That's what I'm complaining about ... they're charging good money for
outdated stuff and passing it off on the unsuspecting who assume it
"must be great, 'cause it came from the ARRL."

(snipped the part where Gary (pretty much) says that the book was poor
in most respects, but gave him one good idea, and since it's the only
amateur book on spread spectrum, it'll have to do ...)

>There are some professional level texts out there on spread

Agreed about the chip manufacturer's app notes ... isn't that where we
started on this one??? <grin>

I just have problems with the hype from the publishing empire on what
seems to me to be predominantly second-rate, outdated material.
(what's the big surprise? ... I'm obviously not very happy with the ARRL
in most respects ... but there's a lot of that going around)

You want to do WHAT??? You would be pulling about 200+ amps out of your car battery, assuming you could
get transistors to switch that much current. You might do better to get some really large F.E.T.s and run
them in a parallel arrangement feeding a charge pump with synchronous rectifiers (more F.E.T.s) to bring
the voltage up to +/- 160 volts. Then use a switched chopper arrangement to make a pseudo sine wave at 60
Hz with a heavy duty filter on the output. I use a 100 amp police alternator on my car with a SEMI
truck/Tractor battery (1300 CCA) in the trunk and even I would think twice about this. Even with the
engine running and the alternator putting out 100 amps if you talked too much you could still discharge
the battery. Of course by then, everything else would probably suffer a meltdown.

If you want to use strictly magnetics at 60 Hz, prepare for some large amounts of metal. Maybe you could
use high frequency magnetic ferrites at above 100KHz to provide +/- 160 volts and switch it from there but
you are describing one Hell of a project.

All said and done, you might be better off buying a portable gasoline powered emergency generator.

One last item, some years back, Lincoln or somebody like that offered a 120 volt alternator designed for
rear window defrosting, but I don't think it had that much wattage. Some SEMI-truck and Large Caterpillar
alternators will put out up to 250 amps at 12 volts but probably cost a ton of money.

I can offer help, but here I will offer a good luck wish.

Lot's of stuff cut out.

Have you tried looking into a tunnel diode or gunn diode oscillator circuit? Due to the reverse impdance
at critical voltage they oscillate, they have to, and I have used tunnel diodes this way before. What you
did not state was what 'good' stability defines. I once made an FM transmitter with about 5 parts that was
good for about 100 feet using a tunnel diode. Problem is that I don't know how easy they are to get
anymore since more modern variants have come along. GUNN diodes maybe, but these are mostly RADAR type
diodes and may be more expensive.

Good luck at any rate.

I needed a noninductive variable resistor to balance an RF bridge up to
200MHz to measure crystals. The sucessful solution was to temperature
control a thermistor, employing temperature to adjust resistance. Use
NTC thermistor, mount two thermistors and a heater on a block.

> 73 de Pete WA5JCI

I am not aware of any power diodes made at 25 kV, which makes me suspect they are in fact more liekly to be a number of diodes in series. If this is the case, the turn-on voltage might be well over the 0.7 V, and so is significant compared to 13.8 V. In that case, the current you used might be well under 1.38 A.

I need a resistor of 10 Ohms in series with the anode supply to a tube taking 2A max. Hence the resistor needs to be 40 W. However, in the event of a tube arc, I do not want the resistor to fuse, so it must take the full HT (5kV) for a short time. This imples it must dissipate 500,000 W. Clearly, I'm not going to buy a 500 kW resistor, so I'm wondering what is the best choice to find a resistor(s) to withstand this without going bang. I have 3 options:

1) Buy one big (say 300 W) resistor at 10 Ohms.
2) Put lots of lower powered resistors in parallel
3) Put lots of lower powered resistors in series.

Any ideas on what is the best bet ? What combination is likely to be able to withstand short duration overloads better, assuming all combinations have the same continuous rating ? My hunch is that one big resistor is not the way to go, since the intense heat cant escape as quickly, but I could well be wrong.

I once saw a book on fixed resistors, and wondered why anyone would write such a book. Perhaps I now wish I had a copy on my bookshelf!

Sorry, I mean the resistor must dissipate 2.5 MW, not 500 kW!

Hi everyone,

I'm very interested in finding a design for an X-band (10GHz) stripline transistor-source, with a varactor for PLL-ing and frequency modulation. I'm planning to use this as a building block in an X-band AX25-interlink, with a high baudrate (10Mb/s). Postscript-layouts with parts-list would be extremely welcome ;) But also any other information you might have.

Regards, 73, Paul Boven.

Text item: Text_1

Has anyone converted the Expo to operation on two meters (voice)?
What is the crystal frequency formulas?

I have a full compliment of test equipment but would love to get any
info available.

Thanks, Bud W4HXP

Why won't a fuse work for this? Surely someone must make a high voltage fuse
which could be utilized.

How about putting a 5 amp or so fuse in series with the
resistor. If the tube fails it will blow the fuse and not the resistor.

Several inverters already exist for probably a lot less in time, effort, and money than you're talking about, and, yes, we're talking about 250 Amps D.C. for 2500 Watts at 12 Volts. There are also 24 volt inverters that use less current. Some of them also charge the batteries at high currents from 120 VAC.

Some inverter companys are:

How about using metal oxide varistors across the resistor and fusing the low side of the high voltage power supply? I know this will not protect the tube in loss of HV and still having drive applied. But you could interlock the HV supply to the input relay.

>Why won't a fuse work for this?

Because the fuse protection is somewhere else. The purpose of the resistor is to limit the maximum possible current that can flow (AKA the prospective current), so the resistor is intended NOT to blow.

With supplies of up to 3kV off-load, I've had good luck with 100W metal-cased wirewound resistors, about 25 ohms per kV of off-load voltage. Although these resistors are not rated for transient high voltages from end to end, or for transient power overloads, they seem to handle the surge current for as long as it takes to blow the fuse or trip the breaker.

It's best to mount the resistor on teflon pillars to avoid any problems with voltage breakdown between the element and the metal case. Obviously there is no point in bolting the case to a heatsink, because it would never dissipate the heat within the timescales we're talking about.

You have another choice. Purchase the correct resistor.

This was one of the sore spots in AG6K's articles Dave. He suggested using a fuse or incorrect resistor types..... of course neither is good.

Fuses are notoriously unreliable, and allow peak current of several hundred to many thousands of amperes to flow during a fault while they internally heat, melt, and the metallic vapor is pushed out of the way by falling sand (if you bought a good HV type fuse). If you used a cheap LV fuse, it may just coat the glass with metalic deposits and arc until the glass explodes. Fuses are best used as a last resort to prevent wiring fires when something fails, but I'm sure you know that.

A wire wound resistor also presents another problem. It has a voltage rating from lead to lead. If that voltage is exceeded, the resistor arcs internally from turn to turn and......zap! No protection until the resistor explodes in a molten internal firestorm.

The correct component is a high energy type of resistor, like a carborundum types used in dummy loads. They have a long arc path, and easily withstand the energy storage of a HV supply. I use a 50 ohm 250 watt resistor in the anode supply of my 3CPX5000, along with a feedback loop that disconnects the triacs on the power mains during a fault. I can

drop a screwdriver across the anode and the only penalty is a loud snap and a tiny pit in the blade.

In a larger 50 kVA supply I used a dump tube to ground the anode during a fault, and it wouldn't even mark the blade during a discharge...just a tiny "tick" and it was off.

Even without opening the mains electronically, a fast circuit breaker and a large anode resistor will work. Be sure to use the correct value, ten ohms seems hardly enough for a 3 kV supply. And remember, you have the ESR of the capacitors and plate choke to help with surge limiting.

If you're gonna use protection, be sure it's a quality component that fits the application properly.

Source record: 102720

I was poking around in the garage the other day, looking
for my old crystal set stuff and I came across a box of tubes.
Yeah, tubes. Some people will keep anything.

Anyway, I picked the box up and took it into the radio shack/
outhouse and tested the filaments. There were a handful of
6SK7 stuff that didn't have filaments. I think I fried them
about 20-odd years ago with a miswired power plug. Ninety volts
don't like filaments. So those were toasts. (My wife asked me
why I didn't throw 'em away. Hell, they's history. I can't
trashcan history, can I?!)

I have a couple 1625s, which might make for an interesting
chirp generator or something. And there's a couple 41s. Yeah,
41s. Like in grandpa's old console set what sat in the parlor.
Back before Cousin Newt put that satellite dish in next to
the outhouse. And a 837.

Neat things about this stuff is it's big enough for me to
see without takin' off my glasses. I do that a lot when I
work on transistor stuff. That and my hands shaking from not
enough espresso make building stuff difficult.

So is it worth it, or should I just put 'em tubes back into
the box and wait for my kids to try and figger out what to
do with 'em at the estate auction?

I'd like to build a 30m tube transmitter and a matching 30m
regen receiver with one stage of audio amplification. I think
I can do that with the three working 6V6s and the 1625. Or
really go loonie and use the 829 B. I think that's it. The
single-envelope dual-pentode with internal self-neutralization.
Came out of a surplus rig, now that I think of it. And
I still have that ART13 down in the basement. Hmmm.....

I don't know much about transmitting tubes but I had a similar issue on
a airborne CRT display that operated at 14KV. We found that:

1. Resistors that are spec'd to operate at that voltage are rare and
expensive. Also, you are looking for an energy rating (Volts * Amps *
Time) and almost no? supplier specifies that.

2. Carbon comp resistors are the "best" at dissipating large amounts of
energy and turning it into heat. The would get hot, emit smoke even,
but when the cooled down they were pretty much resistors still. Too bad
nobody makes carbon comp resistors anymore. A 2 Watt carbon comp
resistor potted correctly will standoff 14KV at altitude.

3. Metal film resistors emit light instead of dissipating the energy.
The stopped being resistors after the event.

4. Wirewound resistors would arc between the spiral wraps of the
conductor. I've seen wirewound resistors specified in volts per inch or
resistor. An acceptable wirewound resistor would have been too large
for our application.

5. Metal oxide resistors were next best at energy dissipation.

Your mileage may vary. We were looking for resistors that would
dissipate a large amount of energy once in a while in an application

that had almost zero power dissipation except during the arc.

MOVs are exactly what you *don't* want - something that effectively
shorts out the current limiting resistor.

Why won't a fuse work for this? Surely someone must make a high voltage fuse
which could be utilized.

>from 100 to 1000 Ohms, tunable to about 1 Ohm, stable to 0.1 milliOhm,
>that's mostly a resistor at 10 MHz?

I needed a noninductive variable resistor to balance an RF bridge up to
200MHz to measure crystals. The sucessful solution was to temperature
control a thermistor, employing temperature to adjust resistance. Use
NTC thermistor, mount two thermistors and a heater on a block.

Hi Bob,

In article <322D2264.9E520A@primenet.com>, Bob Doyle <doyle@primenet.com>
writes:

>
>1. Resistors that are spec'd to operate at that voltage are rare and
>expensive. Also, you are looking for an energy rating (Volts * Amps *
>Time) and almost no? supplier specifies that.

Several suppliers do, but they are hard to find. I liken this problem to
one of finding the correct choke, just try to find manufacturers with the
specs you need. It's cheaper just to sample and test 'til you find one!

I have dozens of different values here in my mess (I mean "lab").
Even RCD, the company that makes all the little metal and carbon film
resistors, can supply energy absorbing resistors. The big mama's all come
from Stackpole now that Carborundum is SK..

>2. Carbon comp resistors are the "best" at dissipating large amounts of
>energy and turning it into heat. The would get hot, emit smoke even,
>but when the cooled down they were pretty much resistors still. Too bad
>nobody makes carbon comp resistors anymore. A 2 Watt carbon comp
>resistor potted correctly will standoff 14KV at altitude.

Still do. I get them from Allen Bradly and Stack Pole.

>3. Metal film resistors emit light instead of dissipating the energy.
>The stopped being resistors after the event.

As you say, not the resistor of choice in this application. The light
doesn't bother me, the noise and flying parts do. The circuit is mostly
bothered by the sustained arc.

>4. Wirewound resistors would arc between the spiral wraps of the
>conductor. I've seen wirewound resistors specified in volts per inch or
>resistor. An acceptable wirewound resistor would have been too large
>for our application.

Right on! That was my earlier point. ALL resistors have a peak voltage
breakdown limit from lead to lead. It's usually around 700 volts with a 5
or ten watt wirewound, and much less with a 1/4 or 1/2 watt.

Now think of this..... Inductance when used as a parasitic suppressor.
The only real low inductance resistor is a carbon comp type, and almost no
one makes them except Allen Bradly. I specify them for parasitic
suppressors AND small energy absorbing applications....but *not* in
applications where resistance drift is critical or long term excessive

temperature operation is expected.

If you dissect the component, you can estimate how good it will be at any of these chores. If it has a thick resistive media, it'll be good. If it has a resistive media that is thin, or has spiral winding, it'll be poor.

If it's a semiconductor like carbon it will eventually decrease in value with sustained overloads. NEVER use carbon resistor for bleeders, and avoid them for voltage dropping unless they never get warm.

In article <322A2F32.5AD1@erols.com>, Larry Minnis <wb6vgi@erols.com>
writes:

>Bill Orr, W6SAI, has such an amp in his Radio Handbook, 17th edition,
>on page682. He has the tubes configured as low-mu triodes. If he says
>it can be done, I for for one would believe him. Larry, WB6VGI.
>

I wouldn't without careful consideration of potential problems. All
suggestions you might find in books aren't always good.

One of Orr's "favorite" tactics is connecting the control grid to the
cathode. He suggests doing this in sweep tube amps even though it results
in feedback levels that de-stabilize the amplifier and send IMD through
the ceiling.

Anyone owning a Dentron GLA1000 or an Amp Supply LA-1000 can see this
problem... just set the amp to 15 or ten meters open the input port and
tune the tank to resonance with the loading control meshed. The amp will
oscillate like crazy. Measure IMD performance and it is over seven dB
worse with the cathode and grid connected, as opposed to conventional "all
grids grounded" operation.

When cathode driven, the control grid is the primary shield between the
input and output. The control grid belongs at low RF potential to ground.

When tubes are designed great care is taken in grid design to be sure IMD
is acceptable. Changing the mode of operation by not using the grid
designed to do the control function, and exciting the grid designed to be
operated at a high dc potential, might not be the best idea if distortion
is a concern.

"Speaking of VLF; I hope the FCC doesn't move the 1750m band (160-190kHz) from Part 15 to Part 97. Limited transmissions are currently allowed without a license at 1750 meters, and experimenters have developed advanced techniques to deal with this noisy band. It would be a shame if this became an amateur band that was restricted to licensed Morse code junkies.

Paul, KC7CKU"

I agree it shouldn't be *restricted* to CW junkies. However, I am all in favor of changing the rules to permit more than 1 watt input and more than 15 m of transmission line + antenna + ground lead combined. If they *need* to give us a CW test for that, fine. But let the part-15ers be.

FWIW I'm an Extra who sees both the enjoyment in using, and also the silliness in requiring, CW.

>should take care of it until the protection interupts the current.

A fuse won't work reliabily, they carry fault currents ten's to thousand's
of times the rated current before failing. Typically fuses have failure
times of 30 seconds to HOURS with a 100% overload. Circuit breakers are
much faster.

In any event, it's energy stored in the capacitors that are the real
problem...not the power line current.

The VHF Expo was manufactored in three band spacings. 136-150.8 Mhz, 150.8-a62 Mhz, and 162-174 Mhz. They will not work very well outside these band spacings. Also, the Expo's I work on are very bad about frequency drifting and require either a jig for calibration, or old case with holes bored in it to get to the calibration points, or a whole lot of taking it in and out of its case and making frequency adjustments.

>rather than passing off "yesterday's news" as "what's hot for tomorrow."

It's not "yesterday's news" in amateur radio. *No one* else is
publishing *anything* for amateurs about SS technique. This is
the hottest SOTA book available for radio amateurs on SS. The
professional books, many of which are as old or older, don't offer
the sort of concrete examples an amateur audience needs. And the
manufacturer's app notes don't have the background an amateur
needs to understand what they're offering.

>>(*If* you have a competent professional writer, and *if* you

>That's what I'm complaining about ... they're charging good money for
>outdated stuff and passing it off on the unsuspecting who assume it
>"must be great, 'cause it came from the ARRL."

That "good money" is about 1/4th or less of what the professional
houses charge for one of their books, and those places aren't
publishing *anything* for radio amateurs. The ARRL technical books
are *cheap* by professional book standards, and they are chock full
of the concrete circuits amateur level audiences need. The ARRL books
aren't aimed at the professional audience (though there's some
profit in reading some of them even if you are a professional).
They're aimed at an amateur audience, IE semi-literate technicians.
And they're written by amateurs, IE other semi-literate technicians
who've actually *tried out* the things they write about. The theory
may be hazy in places, but at least they show you something that
works.

>(snipped the part where Gary (pretty much) says that the book was poor

>
>I just have problems with the hype from the publishing empire on what
>seems to me to be predominantly second-rate, outdated material.
>(what's the big surprise? ... I'm obviously not very happy with the ARRL
>in most respects ... but there's a lot of that going around)

Not from this corner. I don't have a lot of nice things to say about
the ARRL as a political body, but their publications are one thing
that they do adequately *for their intended audience*. *I* only found
one circuit idea in the book which was novel to me, but then I'm not
starting out with a zero knowledge base in SS. The average amateur who
buys this book *is* starting from zero. In that regard, the book does
an adequate job of introducing the concepts and giving concrete circuit
examples. The intended audience for this book would have *no clue*
if they started with the manufacturer's app notes.

Now I cringe at the literacy of some of the writing, and wish that
the authors had more coherent theoretical explanations from time to
time, but it isn't bad considering the intended audience, and it
doesn't cost $100 as some of my professional level books do. Not
all of them are well written either. For every gem like Wilson's
Digital Modulation and Coding, there are dozens of professional
level books where you go "huh?" after reading a chapter twice. In
many cases, if you don't *already* understand the material, you
won't be able to figure out what the author is trying to say.
I've wasted thousands of dollars on books like that (fortunately
tax deductable). At least with the ARRL books I get working circuit
designs (however dated) to examine. That often tells me more than
pages of semi-literate text.

(Anyone with pretentions of understanding the theory underpinning
digital signaling will do himself a big favor by buying a copy of
Wilson. I can't say enough about how well this book is written.
Don't expect any schematics, however. This is a pure theory book.)

Now I find the RSGB books marvels of literacy and good coherent
editing by contrast to the ARRL publications, but the RSGB books

are for the most part even more dated than the ARRL pubs. I feel like I'm in a time warp every time I open one. I still enjoy them, though, and often learn something by reading them. I'd like it if the ARRL could match the clarity and coherence of the RSGB books, but not at the cost of being 20 years out of date instead of only 10.

Hello!

You are invited to participate in the most exciting telecommunications
MLM opportunity! FreedomStarr Communications, Inc. (FCI),
proudly announces our "Share the Wealth" true residual income
program that will go RIGHT ALONG with any MLM program you're
participating in currently, and any business venture you undertake at any
time in the future. It's free! No Cost - No Work - No Risk! FREE
Web Page and a low-cost Internet Package, plus more!

As an FCI representative, you have the chance to build a truly long
term, year-after-year, monthly residual income, with minimal effort. With
the TOLL FREE, 24 HOUR AUTOMATIC VOICE MAIL SPONSORING SYSTEM,
you may build an EFFORTLESS, UNLIMITED RESIDUAL INCOME in the
$100+ BILLION per year telecommunications industry.

Imagine earning a steady, long-term, monthly residual income check
from the long distance telephone usage of THOUSANDS of other
people! If you were to refer just 4 other people to FCI by having them
call our Toll Free Recorded Hot Line, and they were to duplicate your
efforts, you will have built for yourself an ongoing monthly residual
imcome of over $4000!!!! (This is based on a smaill $20.00 average
monthly interstate long distance phone bill). You can imagine the
potential!!!!

And, here's the best part - our RECORDED INFORMATION &
REGISTRATION HOT LINE WILL DO ALL OF THE WORK FOR YOU!
Our state-of-the-art 800 Voice mail System can handle up to
256 SIMULTANEOUS CALLS from every state in the nation!

Call FCI's state of the art FAX ON DEMAND system first and see how
EASY and POWERFUL this GREAT once in a life time opportunity can
be! CALL the fax at 619-432-9700!!!

The Fax on Demand is less than 10 pages. You must use your hand set
and the fax must be in manual mode when you call.

This means that this program is perfectly suited for the ELECTRONIC MARKETING that you could or and ALREADY doing.

$$$ Call the FREE information HOT LINE NOW to find out how to get your ID# registered FREE! and find out more about this one in a LIFETIME GREAT OPPORTUNITY! It's a FREE call, and it's FREE to join! What do you have to lose! $$$$

1-800-223-6477 (Sponsor #: va1123581)

Your FCI ID# consists of the FIRST 2 LETTERS of your LAST NAME, followed by the LAST 7 DIGITS of your social Security Number. For Example, if your name is Tom James, and your SS# is 123456789, then your FCI ID# would be: JA3456789 (NOT TJ3456789).

After your registration phone call, you may IMMEDIATELY begin referring others to the same toll free phone number, and get credit for those referrals, through 6 computer-tracked levels of your growing organization. In 2 to 3 days, you will receive more information, registration forms, and a sample FCI glossy brochure in the mail.

Every month, you may receive a printed down line report showing every person who has called using your sponsor ID#, and every person signed on from levels 2 through 6.

This is the OPPORTUNITY OF A LIGETIME! You'll be one of the FIRST 1000 PEOPLE IN THE U.S.A., which means that your chance of earning a SERIOUS MONTHLY INCOME in a very short period of time is very realistic! We are looking for individuals such as yourself, to reach our goal of 50,000 representatives by January 1, 1997.

Here was the clincher for me! U.S. Residents note: In order to be a part of this outstanding program you DO NOT have to switch your Long Distance sservice to FCI, if you are getting a better rate, or the phone is not in your name, or for whatever reason you have. (You can prove a better rate by submitting a photocopy of your bill). If your are not switching carriers you only need to remit $20 (annually) for YOUR monthly down line report.

MORE INFORMATION FOR YOU:

Overview: Who is 1)WilTel, 2) UniDial, and 3) FCI?

1) Founded in 1985, WilTel owns and operates a nationwide fiber-optic network, on of only four in the United States, with access to more than 30,000 system mils. WilTel pioneered the techinique of pulling fiber-optic cables through decommissioned oil and gas pipelines. This approach results in the most secure routes in the industry, and as a result, over one half of the U.S.A.'s Fortune 100 corporations trust and utilize WilTel as their long distance carrier. as a full service telecommunications company, WilTel provices data, voice, and video products and services worldwide and is currently the fourth largest long distance carrier in the U.S.A.

2) UniDial, Inc. is the largest re-seller for WilTel, having signed a $480 million long-term agreement on June 5th, 1995 - the largest ever in re-seller history. this strategic partnership demonstarates UniDial's aggressive plan to penetrate the re-seller market, which is growing by leaps and bounds. In 1994, the re-seller industry reached $8.25 billion, and is expected to increase to more than $12 billion by 1998.

By taking advantage of UniDial's massive buying power, individuals such as yourself now have access to a fabulous new long distance rate. If you are currently using AT&T, MCI, Sprint or onne of the other long distance services you might by paying as much as 27 cents per minute for your long distance calls.

You may now call anytime, for 12.9 cents per minute (Interstate) with absolutely no minimum commitment and you don't have to wait until 5:00 pm to get this great, low rate! Also, there will be no change in the way you place a long distance call - just dial 1+ the area code and phone number.

The UniDial "Global Axcess" Communications Card is now available. Features include with the Global Axcess card are 800# Voice Mail, Fax Mail, international calling (at savings up to 55% savings over AT&T, MCI, and Sprint), Speed Dialing, and Coference Calling without an operator. You can use the Axcess card from any of over 30 foreign countries. this is what I call a company that listens to the needs of entrepreneurs like us.

FreedomStarr Communications, Inc. is a telecommunications network marketing company representing UniDial, Inc. Our firm provides marketing support and an ingenious distribution mechanism to a network of independent "customer/representatives" all over the United states of America.

FCI offers US citizens a very simple, yet powerful way to both save money and earn a substantial long term residual income in the exciting telecommunications industry, with very little effort aside from sharing a toll free recorded hot line phone number with others. Because of the simplicity of FCI's Share the Wealth program, no sales ability of experience is required. In fact, you may build your income without ever speaking with another human being! This revolutionary new concept is taking the nation by storm, and we welcome you and invite you to become a part of our success.

**** YOUR SUCCESS IS OUR SUCCESS ****

Do you understand Moxon's books and articles? There are many places in his writings where I say "duh".

Alot of the RSGB stuff is hard to read because of the difference in word meanings and your "time warp" effect.

My $.02 worth.

I have seen some HP beam lead devices in the Newark Electronics catalog
for $15 to $30 each. But for really high frequency nothing beats
the "old fashion" germanium point contact diodes. They can detect
up to 300GHz, but I don't know the details. Just read that in
a book on microwave measurement techniques. For example, I am
not sure if the 1N23 diodes you find in old waveguide detectors
will go this high or not. They certainly wont give a good 50 ohm
match at that frequency.

General hint for this kind of thing: use a dipole antenna tuned to
the frequency of interest to increase your sensitivity.

I fully agree that the 1750 meter band should be left alone BUT with a power increase to some nominal value between ten and one hundred watts. I have been running a BPSK beacon on 187.65 for years emulating what has been done for submarines. We do not need any further restrictions---even those created by ham bands as no restrictions exists now! Cliff K7RR

Careful here. I don't have the 17th edition, but I do have the 22nd and it has an amplifier design just as Tom suggests. Cathode-driven with normal grid and screen bias applied.

Also note, most of the circuits in these books are stolen from somebody else, (I know, I'm one of them) and have not necessarily been approved (or proved) by either Bill Orr or EIMAC.

Hi Bob,

In article <322D2264.9E520A@primenet.com>, Bob Doyle <doyle@primenet.com>
writes:

>
>1. Resistors that are spec'd to operate at that voltage are rare and
>expensive. Also, you are looking for an energy rating (Volts * Amps *
>Time) and almost no? supplier specifies that.

Several suppliers do, but they are hard to find. I liken this problem to
one of finding the correct choke, just try to find manufacturers with the
specs you need. It's cheaper just to sample and test 'til you find one!

I have dozens of different values here in my mess (I mean "lab").
Even RCD, the company that makes all the little metal and carbon film
resistors, can supply energy absorbing resistors. The big mama's all come
from Stackpole now that Carborundum is SK..

>2. Carbon comp resistors are the "best" at dissipating large amounts of
>energy and turning it into heat. The would get hot, emit smoke even,
>but when the cooled down they were pretty much resistors still. Too bad
>nobody makes carbon comp resistors anymore. A 2 Watt carbon comp
>resistor potted correctly will standoff 14KV at altitude.

Still do. I get them from Allen Bradly and Stack Pole.

>3. Metal film resistors emit light instead of dissipating the energy.
>The stopped being resistors after the event.

As you say, not the resistor of choice in this application. The light
doesn't bother me, the noise and flying parts do. The circuit is mostly
bothered by the sustained arc.

>4. Wirewound resistors would arc between the spiral wraps of the
>conductor. I've seen wirewound resistors specified in volts per inch or
>resistor. An acceptable wirewound resistor would have been too large
>for our application.

Right on! That was my earlier point. ALL resistors have a peak voltage
breakdown limit from lead to lead. It's usually around 700 volts with a 5
or ten watt wirewound, and much less with a 1/4 or 1/2 watt.

Now think of this..... Inductance when used as a parasitic suppressor. The only real low inductance resistor is a carbon comp type, and almost no one makes them except Allen Bradly. I specify them for parasitic suppressors AND small energy absorbing applications....but *not* in applications where resistance drift is critical or long term excessive temperature operation is expected.

If you dissect the component, you can estimate how good it will be at any of these chores. If it has a thick resistive media, it'll be good. If it has a resistive media that is thin, or has spiral winding, it'll be poor.

If it's a semiconductor like carbon it will eventually decrease in value with sustained overloads. NEVER use carbon resistor for bleeders, and avoid them for voltage dropping unless they never get warm.

> Mark

I seem that if there is an arc-over, the current is going to increase
rapidly and voltage across the resistor will rise rapidly. When this
happens, the voltage across the arc will drop rapidly and the arc will end
quickly. You might have to just look for a type of resistor which will
handle a large but brief surge rather than one which will dissipate 500KW
continuously. That would be one BIG resistor.

No, you are not alone. But you are outnumbered.

Homebrewers are already a minority in the amateur radio community, and those of us interested in state-of-the-art topics are fewer still.

I get a chuckle out of those who claim that Morse code is an appropriate requirement for amateur radio operators. Today Morse code is an arcane mode of communication which is little used outside the amateur radio community.

The FCC expects the amateur service to "...provide for advancing skills in both the communications and technical phases of the art." In my opinion a test of vocabulary, grammar, or spelling makes as much sense as a test for Morse code. Maybe more.

(If Morse code is such an advanced method of communication then why is this discussion taking place on the Internet instead of on the HF band?)

Hand-keyed CW has its place. I'm sure its proponents can get a great deal of satisfaction from using it. And in emergency situations CW can be just as useful as many other modes in the amateur bands. Of course today it's the digital modes that get through when all other modes fail.

So I don't want to take away frequencies set aside for CW. But I do think the Morse requirements are a bit silly.

And today Morse code is not much of an obstacle to anyone interested in the cutting edge. The no-code license opens up many of the amateur bands, and Part 15 operations at VLF or ELF challenge even state-of-the-art equipment. All available to experimenters who don't want to learn the code.

Speaking of VLF; I hope the FCC doesn't move the 1750m band (160-190kHz) from Part 15 to Part 97. Limited transmissions are currently allowed without a license at 1750 meters, and experimenters have developed advanced techniques to deal

with this noisy band. It would be a shame if this became an amateur band that was restricted to licensed Morse code junkies.

I don't have my handbook handy but I have seen one in the radio handbook that
has a gg 4cx??? with bias supplies. However if you read Bill Orr's (W6SAI) EIMAC
Amateur Service Newsletter AS-1 you will notice that he says not to use any
of the
following in gg triode connected service (page 1, paragraph 3):

4-65
4x150
4cx250
4cx1000a

The example he gives is for a 4x150a which dissipates 18 watts in the
control grid which is 9 times the maximum spec.
Others in the 4cx series such as the 4cx350 have a ZERO control grid
dissipation spec.
He does give the specs for a 4-125A, 4-400A and 4-1000A.

Unless you have a very SPECIAL power supply, it will not supply you with
500A
at 5kV! If it could supply that current, you would have to worry about a
lot more
than just your resistor.....

Find out your p/s short circuit current capabilities, calculate the primary
side current,
and fuse appropriately (or provide a protection circuit based on the voltage
drop
across your 10 ohm resistor). The thermal inertia of your carefully
selected resistor
should take care of it until the protection interupts the current.

Source record: 102653

Some screw-stud type power silicon diodes have come
into my possession, but some of them are just not in the several
data and equivalents books I have. Could someone help me
out with basic specs please? eg. Reverse voltage & maximum
current rating. The date codes indicate they were manufactured
in the mid to late '70s.

The manufacturer and type codes are:
GE A327B
NAE 1N1202A
IR 20FQ035
M 1901-0630
M 1-1035
TRW SD51

Please respond via private email.
Thanks in advance,
Glenn <gbaddele@vitgssw.telecom.com.au>

Hi.

I am looking to buy 'junk box stuff' to help replenish my shop. I have been out of ham radio for 12 years, and in that time most of my RF related parts have disappeared. I used to tear apart old transmitters and receivers to get coil forms, toroids, variable caps, and the like but most of those rigs are now collectors items, even in non-working condition.

I much prefer to use 'old' used parts, rather than constantly dig out the 'DigiKey' catalog to buy new ones.

What I am looking for is coils, coil forms, variable caps, remnants of old homebrew projects and long-dead rigs that have useable parts left, etc. Tubes, (!), sockets, verniers, pots, etc. (Transformers weigh too much to ship!). But mostly after coils and other RF components or portions of old gear.

Not the 'new in the box variety', but the old scraggly but ueseable stuff that makes junk boxes famous. Maybe in $10, $20 or $50 'grab bag' assortment boxes, or whatever works for you. Don't go to any bother - just misc parts and remnants in a box. Don't bother to itemize - just a basic description of what you have, and I'll trust you. (I think hams still do that!)

email what you have to:

I guess you are saying that you want to match a voltage generator with
1 ohm impedance to the 3k ohm input of the NE602? I don't think you
need to match impedance, assuming the voltage source is sufficient
in amplitude. It would help to know what you are trying to do exactly.

--High voltage trafos are a problem. If you can't scrape up an old one,
from surplus or hamfests, you have some options:

1) Antique Electronic Supply - sells Hammond replacement power trafos,
complete with 5VAC and 6.3VAC filament windings. Also sells
vacuum tubes, RF chokes, power supply chokes, High-voltage caps,
Hi-Z headphones, tube sockets, audio trafos, variable caps,
radio restoration parts and supplies, and books.
(Antique Electronic Supply, 6221 S. Maple Ave., Tempe, AZ, 85283,
(602)820-4643 or FAX(800)706-6789 - catalog was free)

2) Electronic wholesalers sell isolation trafos in various VA ratings,
with 115VAC or 230VAC secondaries. 110VAC is sufficient for regens.
230VAC is enough for a low powered 6V6 oscillator or MOPA rig.
Radio Shack sells small transformers for low-voltage power supplies.
These 12.6VAC secondaries are center-tapped for 6.3VAC. Really, I
guess they are filament trafos.

3) The Radio Shack trafos can be wired back-to-back in pairs to achieve
an isolation trafo with 110VAC secondary (Connect 12.6VAC secondaries
in parallel, in-phase. Use one trafo primary as the 110VAC
secondary, take 6.3VAC for filaments from the tied-together windings.)

>

Avantek do two ranges of VCO's running up beyond 10GHz, one using
varactor diodes to vary the frequency, and the other chunks of YIG
(yttrium-aluminium garnet). The varactor-tuned parts were cheaper and
could be modulated faster. When I last looked the YIG-tuned parts cost
some hundreds of guilders.

Avantek is on the net (more or less) - see http:/www.penstock.avnet.com/
new.htm - but they haven't got their data sheets accessible yet.

I've got a 1990 catalogue at home (I think) and I'll e-mail you some
part numbers this evening.

I guess that you are aware that conventional pcb materials both
absorb and disperse at above about 500MHz, so you will need to buld the
10GHz parts of your circuit on some sort of microwave substrate.

>Dave, n2fam
>(a Kenwood fan but also a Yaesu and Ten-Tec fan...)

Failing Kenwood supplying the paint (I somehow doubt they will be very obliging) here's what I do:

A local automotive supply chain here in Toronto (Canadian Tire) carries a large selection of car touch up spray paint. They carry OEM paints for most automakers' original colours.
The colour that I needed was a sort of grey with a hint of olive.
Of the 2 times that I decided to repaint a radio case I had little trouble coming up with a near match.

I spend a little extra time preparing the case before painting by sanding out any scratches and very carefully hammering out any dents. After painting, I oven bake the covers in the kitchen.
Of course, ventilate the kitchen during the bake and air it out afterwards.

Cheers,
Hugh Duff VA3TO Toronto

> > this without going bang.

Actually, Dave, the calculation of the power rating of the resistor is a bit more complicated
than estimating the peak power from V^2/R. As you noted, when the tube arcs, the full power supply voltage drops across the resistor. As has already been noted, however, unless you have
a HUMONGOUS power supply, the supply won't be able to supply the 500A of current to the resistor. There are, in fact, two characteristic currents you need to consider.

The first is the "steady-state" current, which is the current the supply can deliver in the steady state when the output voltage is short-circuited to ground. This steady-state value is
limited by the resistance of the transformer windings and the mutual inductance between the primary and secondary. This steady state current is probably in the range 10-50 amps. However, a fuse or circuit breaker will (hopefully!) trip before the steady state current is
reached, so the steady-state current is largely a theoretical consideration.

The other relevant current is the peak current delivered to the resistor when the tube arc occurs. This current is much higher than the steady-state current, and is caused by the stored energy in the filter capacitors discharging through your 10 ohm current-limiting resistor. The amount of stored energy is given by CV^2/2 (joules), where C is the filter capacitance and V is the (5KV) power supply voltage. This energy corresponds to a charge stored on the capacitor of Q=CV (coulombs), and when the tube arc occurs, this charge decays
to ground through the 10ohm resistor with a time constant RC. A typical value for RC would be
(30uF)(10ohms)=300usec

The current associated with this discharge also decays exponentially through the resistor with the same time constant. The peak instanteous value of the current is given theoretically
by V/R, but because the time constant is so short, the actual instanteous current would be reduced by the inductance of the power supply leads and other stray inductance. I'm guessing
the actual peak current would be about 100-200A, but it would be in this range for less

than
a millisecond.

As a practical matter, I normally use a 0.82-2.0 ohm 2Watt wire wound resistor for current limiting purposes. The resistor explodes if a tube arc occurs, thus limiting damage to the amplifier. I have also used a 50 ohm 50W wirewound resistor BEFORE the filter capacitors, to
limit the charging current through the capacitor when the supply is first turned on, but it isn't really necessary if you use a (recommended) step-start circuit.

: What i don't know is the voltage on the + and - terminals of the
: "type A" battery. : HELP?!? : e-mail to Jay_Ritch@msn.com

First, probably the 22.5 vdc is a "C" battery (grid bias). If so,
then it is conected as -22.5 vdc.

The main problem is the "A" battery. That lights the filaments of the
tubes. You can determine this by looking up the tube types in a manual
and finding the filament voltage specification. If you don't have a
manual, email me the tube type numbers and I may be able to look them up.
At that time, the type 24A, 27, and 45 were popular tubes.

During the late 40's, while in high school, I had fun playing with junk
radios from he 30's. They were, of course, hand wired so you should be
able to trace the wires from the +A and -A leads to check that they did
not do a mix series and parallel wiring.

>Sorry, I mean the resistor must dissipate 2.5 MW, not 500 kW!

It will only dissipate this if your power supply can supply 5KV/10ohms = 500A

If you limit the PSU current to 2A, then you need only dissipate 10KW. If it's only a short time (how short? mS? uS?) then you may be able to get away with a much lower power rating. The main worry that you may have is arcing between turns of the resistor element unless it is a composition type.

989. More tubes & more transformers & more snide social commentary

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-05 00:00:00 UTC
From: nyoung@desire.wright.edu
Message-ID: <1996Sep5.132847@desire.wright.edu>
Source record: 102669

Well, where _would_ I get filament and plate
voltage transformers these here days? The filament
transformer is easy: Radio Shack. They have a couple
different 12.5 Volt center-tapped transformers that
would likely have enough hoos to light the filaments.
Maybe 5 A would do, seems to me.

Plate transformers are another matter, since it's
dagnab hard to find that sort of stuff now. WHich means
that I would have to do the flea market/surplus radio
search. Here in the Dayton, OH area we have the always
popular Mendelson's Surplus. Spend a couple days in there
looking for stuff what ain't where the sign says it would
be. ANd Midwest Surplus in Fairborn might have the stuff,
since they have a big pile of transformers... and you
can see what they are and don't have to wander around
to find 'em.

The rest of the stuff I'd drag out of old radios
what don't work no more. Easy part, that. Besides,
I've been blowing stuff up pretty much non-stop since
I was 12, so I have a big box of blown up stuff that
has trashformers and suchlike stuff in it. Even tubes.

I still like not havin' to take off my glasses and
get out the microfilament interlaminar exoskeleton
cosmic dry-ice evaporated vacuum gold-plated zee-tron
microscope to look at the resistor codes. Ah, the joys
of being old enough to know what to do with all this
old stuff that young whipper-snapper engineering
dreamer types can't even figure which end goes in the
socket.

That and tapioca.

>won't last long on battery power!). All I have in the junk box is 2N3866, but
>I'm sure there must be better transistors by now!

Well, you've got several factors to consider.

First of all, the amount of bias power in a transistor does influence
the IP3/IMD performance, but, for every transistor, there is a point
where you stop gaining improved IP3 for increased bias power. So,
for any transistor you select, the bias point should be selected
for the best IP3, not based on some pre-conceived notion of
bias level.

The desire for low noise is almost certainly going to trade-off
against the necessity for good mixer termination (assuming you use
a mixer that requires good termination). You can't just select
a transistor on the basis of NFopt (the optimal noise figure), since
this represents the best possible performance, usually at a
significant mis-match. You need to evaluate transistors in
a circuit which meets the requirements, and you'll find that
even very low-noise parts aren't that important.

Is a "low noise" stage *really* necessary here? Have you done a
cascade noise/gain analysis on the proposed receiver? My personal
slant is to distribute gain and loss in the front end in such a
way that most of the system gain comes after the first IF 'roofing'
filter. The post-mixer amplifier really exists to provide good
termination for the mixer and compensate for loss in the IF roofing
filter.

I'd suggest that the classic 2N5109 stage, biased at something
like 50mA/8Vce, with a gain of 10dB or so is probably more than
enough. If the system NF isn't good enough, try using a strong
low-noise RF amplifier before the mixer. In any event, CATV transistors
are the low-IMD parts, since cable TV consists of a great number of
signals just eager to mix.

If you want to keep running the radio off batteries (as was originally designed) you can make your own C and B batteries using series combinations of 9V batteries purchased from bulk supply stores like Costco etc. I have made some 90V B batteries for a Transocianic using that method. The contacts are easy to solder to and the batteries last quite a while since the current draw is low.

994. Simple (Inexpensive) Radio Kits?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-05 00:00:00 UTC
From: n2tkx@aol.com
Message-ID: <50ndol$189@newsbf02.news.aol.com>
Source record: 102674

Does anyone know of a source for very inexpensive radio kits - like less than $5.00? I've got a bunch of Boy Scouts that want to earn their radio merit badge but one of the requirements is that they construct a radio circuit of some sort - code practice oscillators and crystal sets are ruled out. In the past I've been able to scrounge the parts for a 1-tube receive out of my parts pile but that's reached the end of it's usefulness. I'll probably have the kids buy a kit somewhere but I hate to ask them to spend more than $5.

I'm not familiar with that radio, but check if your library has Riders
or Sams manuals on Microfiche, some do, and check them.

I would recommend staying with batteries, the radio's built to use
batteries don't like even a hint of ripple.

An electronic store that has surplus telephone stuff with have nice
1 1/2 volt cells, to series for filament, if you need more than 1.5
volts.

They will also have 45 and 90 volt cells, with some of 45's tapped for
22 1/2.

Altex in Austin still has Eveready "B" cells, I noticed a while back,
but at 17.50 for 45 volt cell the 9 volts are cheaper but not original.

Good Luck

More Nits: Both right (or both wrong).

The slope DOES go negative (dV/dI < 0) so the differential resistance (or small signal resistance) does indeed go negative. But the resistance (V/I) is always positive.

One way to think of it is that you DC bias the diode in the negative differential resistance region using DC current, then you put a small signal AC circuit around the diode, coupling energy in and out (for an amplifier), or simply making a feedback loop with a narrow band width for an oscillator, and you will get AC signal out with no AC in. But you will always burn up more DC power than the AC signal you get, usually a lot more.

Gunn diodes come from the Gunn effect in bulk GaAs material where the mobility of the electrons slows as the elecectron density increases, forming "wave like" regions of bunched up electrons, called Gunn domains. These have the effect of causing the current to be reduced if the voltage is further increased, thus negative differential impedance. Gunn modes often happened in early GaAs FETs, and these were very undesired,as they could cause spurious oscillations in amplifiers.

G'day,

On 4 Sep 1996, Dean T. Miller wrote:

> But where would you get the high voltage (not to mention filament)
> transformers these days??<BG>

If you have a lot of spare time, you can of course wind them yourself... I usually do this, since it saves a lot of money as compared to buying them, even when you buy in dump-stores. I usually buy my heavy transformers at non-ham flea-markers, so they usually cost no more than 1 or 2 US$. (paid 2$ for a 750W transformer). However, it usually takes a while to wind, even with a home-made winding-machine (very simple, hand driven). In my neighbourhoud there's a transformer/electromotor winding-shop, which can do the job for about 60$. When I do it myself, it takes me about 3 days of 8 hours (on a 500W transformer) of boring work, but then you have a trafo exactly as you wish it, i.e. with 'extra' voltages, filament, grid, screen voltages, etc.

Hope this has been of help,

There was some good info there , but don't follow this advice!!!!!!!!!

I think that was the worse suggestion I've ever heard, short of using a thin piece of wire as a fuse. The use of a fractional ohm to 2 ohm resistor is incorrect in almost any application.

In a typical application using electrolytics, the ESR of the capacitors, the choke resistance and inductance, and other circuit losses would make the 2 watt resistor nothing but a very poor "fuse".... it most certainly would NOT limit current. Just what do you think the big flash is from? Until that sustained arc quits, the resistor is heavily conducting.

Let's look at a pratical example. One 3600 volt supply amplifier has a 6 ohm choke, and a typical minimum ESR of .6 ohms per electrolytic. It has 10.8 ohms of series resistance not including wiring and choke impedance. The peak discharge pulse during an arc will be 200 amperes (or less) in this example due to the accumulation of resistances and impedances, and the addition of a 2 ohm resistor would mean a reduction of surge to 180 amperes or so. Big deal!!!

To add any meaningful protection the surge resistor would have to be a minimum of ten ohms, and preferably something larger. Since the tube used in it can generally take a brief discharge of a few hundred amperes without permanent damge, everything is fine as is.

If the PA used a large oil capacitor and a larger plate choke, the ESR would be as low a fraction of an ohm. The surge current could easily approach 1000 amperes with the suggested two ohm limiter.... that value is useless to protect the tube. If the resistor vaporizes before the grid, you're in luck. Maybe it will, maybe it won't.

Depending on a resistor explosion to shut the system down is not very wise. Fuses are undependable enough for reliability and failure time when overloaded, I'd hate to think of the reliability of a component designed

for a totally different application.

Using a Triac trigger to test small 2 watt resistors, I found some that took a several hundred milliseconds to explode with a 1000 ampere surge. There is actually such a large time lag between overload and explosion resistors can explode AFTER the current dump has decayed!! Some protection that is.

If someone is going to go through all the difficulty to install protection, they might as well use the correct part. It isn't all that difficult. The correct component would LIMIT surge to a safe value for the tube and ALL other components until a breaker could open.

In the length of time it takes for the problem to degenerate to transformer ESR, the expensive damage would already be done. Transformer ESR has little to do with anything past the diodes except voltage regulation.

Where do you put a roll of #10 in a power supply box, hi hi.

It's obvious that the resistor serves a purpose that is very difficult to fill with a roll of magnet wire. A number of responses have indicated that they sometimes fail and act as a fuse. The physical layout of the power supply is not cramped. However, there isn't room for whatever gauge wire would be required. Not replacing the resistor with a resistor would be poor engineering.

As the resistor is $1.00 from Astron and $1.76 from Newark, I went ahead and ordered a handful from Astron.

Amen.

Stealing ideas is bad enough, but the real problem is the idea often gets misapplied because the thief doesn't want to ask WHY something was done. One of my friends there told me he used to lock his desk so his work didn't suddenly appear in a book that some else made money from, usually with the whole concept distorted.

Some guy in Texas grilled me on my phased receiving loops, and published an article that was all wet. It's a curse.

> than $5.00?

No, but you should be able to homebrew a crystal set for about that - $.30 for the 1N34A detector, several bucks for the crystal earphone, $.60 for the 10K resistor and 0.01 uF cap to parallel with the earphone, and $.50 for a fixed 350 pf cap. I'll assume you scavange some fine enameled wire from a TV flyback transformer or some such. Wind a 250 uH coil on a 2" paper mailing tube form and coat it with shellac to keep things together. Take some sheet brass or phosphor-bronze and make a sliding contact for the coil. Sandpaper off the insulation in a 1/4 inch wide strip where the slider makes contact along the coil. Arrange for the sliding contact to short the end of the coil, and you have a variable inductor that you will use to tune the radio, in place of a rather expensive variable capacitor.

Hook the coil and 350 pF cap in parallel and feed the earphone/resistor/0.01 uF capacitor combination through the 1N34A, attach antenna and ground, and voila, you have a radio.

As an alternative, consider using a varactor diode and potentiometer to tune the radio. You could build a little regen set around an MPF102, a home-made coil, a varactor and potentiometer tuning arrangement, and a crystal earphone.

-Steve

There are other devices like the 2N5109 that are better, but the 2N3866
isn't too bad, and is easier to get hold of. A post-mixer amp circuit in
the ARRL Handbook can use both these devices, and I'm using it with a
2N3866, in an experimental Rx, although I have a couple of 2N5109s lying
around.

1014. VT-25A Tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-06 00:00:00 UTC
From: bk296@FreeNet.Carleton.CA
Message-ID: <50pn1m$euj@freenet-news.carleton.ca>
Source record: 102547

The VT-25A tube is listed as a "10Y" or "10 Special" in the literature.
Does anyone know "Y" it is "Special"? Is it just a ruggedized 10?

Thanks for any help.

Wow! I guess great minds are one. I was just about ready to suggest the 2N5109 transistor as well. It was described in just that fashion (first IF following SBL-1 mixer) some years ago in QEX magazine. It might take some digging but it's there!! 73 Cliff Buttschardt K7RR ex W6HDO

1016. PIC Keyer

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-06 00:00:00 UTC
From: Rick Miller <rdmiller@execpc.com>
Message-ID: <01bb9c36$36bddc40$060801c1@eng06.digalogsys.com>
Source record: 102549
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

I've got *working* code for the PIC16C84 to implement an iambic keyer in only
FOUR PARTS:
(1) PIC16C84, which is an 18-pin DIP or SOIC
(1) "ColorBurst" crystal (3.58 MHz) for its clock
(2) small (~22pF, value not critical) capacitors to help the crystal

That's all! NO POTS. When it "wakes up" (power-up or reset) it's in 'menu mode'
and sounds out the menu options in Morse code for you. You browse back and forth through the menu by tapping either paddle, you adjust rate and pitch the same
way. Your current selection is [Enter]'d when you squeeze both. The menu goes like this:

KEY-->Iambic keying, keys the transmitter.
RATE-->Adjust speed.
TONE-->Adjust pitch.
PRACTICE-->Iambic keying, does *not* key the transmitter.
QUIET/SIDETONE-->Toggles sidetone generation from the keyer.

The chip has internal pull-ups on its input pins and debouncing is done in firmware. All configuration options are stored in on-chip non-volatile memory.
The output pin emulates an open-collector output that can sink 25mA.
It needs a DC supply (2.0 to 6.0 Volts DC is fine) and should be capacitively
coupled to your rig's speaker (okay, that's *five* parts with the 0.01uF cap).

Like I said, I've already got this code written and *running*. The problem is that I'm completely new to iambic keying... I have no idea what it's *supposed* to 'feel' like except what I've read in the ARRL Handbook and the Curtis 8044 documentation. That means I'm looking for beta testers!

If anyone is interested in trying this keyer out, just email me: <rdmiller@execpc.com>. If you can program a PIC16C84, I'll send you the HEX file. Otherwise, we might be able to make arrangements to get a pre-programmed PIC16F84 to you. Anyone should be able to come up with the other parts themselves.

Later on, I may offer it as a complete board done in surface-mount which should come out to be a rectangle less than 15mm on a side. By then, the user interface should be somewhat improved and I'll include some Morse memory functionality and beacon-mode operation as well.

Anyone interested?

Rick Miller (kb9obn) rdmiller@execpc.com

1017. Re: 4CX250B as GG TRIODE amp ???

>
>S

Of course that idea was pilfered from the wonderful Collins design used in the 4CX1000 amp they made, and was misapplied in the article. There are several major errors in the super cathode article.

The problems are:

1.) In order to function correctly as the original Collins circuit intended, the tube must NEVER draw grid current. This was overlooked in the article.

2.) The tube must be a multiple grid tube.This was overlooked in the article.

3.) The multiple grid tube must be unconditionally stable with the control grid floating for RF. This was ovelooked in the article.

It's an easy circuit to analyze. If the PA does not follow these guidelines, the super cathode driven circuit does the following:

1.) If the tube draws current over any portion of the RF drve cycle, the sudden drop or change in grid-cathode impedance during grid current causes a change in operating characteristics and a reduction in gain. This forces non-linearity just when it is needed most. The result is higher IMD, not less.

Why did a company like Collins do this? Because the 4CX1000 has a ZERO mA grid current rating. If grid current is ever drawn, it RUINS the tube. Collins did this to prevent overdissipating the grid with a 100 watt exciter, knowing the tube would never have grid current during correct operation.

2.) Because the control grid is "floated" on a high RF impedance, the grid no longer shields the anode and cathode. The additional feedback this causes is regenerative at some frequencies, and destabilizes the PA. If there are extra grids in the tube between the control grid and cathode, they sometimes offer enough shielding to prevent excessive feedback. If

the tube is a triode, stability is ALWAYS compromised with a super cathode driven circuit. The resulting uncontrolled feedback is just as likely to decrease IMD as improve it. The circuit has no place in a triode PA, even a class A triode.

3.) Even with an AB1 tetrode, connecting the grid to the cathode via a voltage divider is unwise UNLESS the PA is completely stable and has more than adequate input to output isolation without grounding the control grid. Feedthrough capacitance has a deleterious effect on performance and stability, and "floating" the grid even the slightest amount will increase this feedback. The 4CX1000A has very good cathode to anode isolation even withoutt depending on the control grid, but other tubes don't.

Heathkit was pushed into using this circuit in the SB-220, and it had detrimental affects on stability and IMD. If you remove the super cathode garbage from the control grids and ground the grids like Eimac intended, the Sb-220 has better IMD performance and gain vs frequency linearity.

You won't find a single paper appoved by Eimac's engineering department on super cathode circuits. None of the recommended circuits in official Eimac publications show grids in 3-500's going anywhere but the chassis for RF. I'd go to real company engineers for critical electrical data, not marketing guys.

A simple resistor in series with the cathode is simpler and really does IMPROVE IMD and stability.

Source record: 102551

Emtech has a new QRP transceiver kit available for only $75, which my ham supply company just started to carry. You can order either the 80, 40,30, or 20 meter version. It is a superhet single signal receiver, with a variable crystal filter (available as an option for $20). The transmiter will put out 4-5 watts max, and adjustable down to the MW range. The keying and muting is very smooth and features solid state antenna switching. The rig also comes with full QSK keying. You supply the cabinet, power plug,and knobs. The rig is guranteed to work, as it is put together and tested in steps, you should not have any surprises. Full e-mail and phone tech support is available if needed.

I haven't even put this item in my products data base yet. Thought I would share it's capabilities with the group here first. If interested send me an e-mail and I'll provided more details. Best of 73's Ray

The problem is, you have a resistor that must be able to handle the discharge of say 100uF at 5kV. It is 10 Ohms. Aside from the obvious solution of making the resistor 100 ohms and only needing to worry about 50A, you could add inductance to reduce the peak current. The real problem is an energetic dissasembly of the resistor with the 500A peak current. You will need a very large resistor, for example a wire wound one, with 18guage wire. Now where can one get one of these? An electric fire element perhaps?

I have a similar surge limiting resistor in my HT PSU. It is 90 ohms and ~100W, made from 5 20W 18 ohm resistors in series to ensure it does not arc. The EHT is 2-2.5 kV, typical current 500mA. Short circuit current ~28A. It has survived. If you were to scale it, assuming you can do that, to say 400W you should be OK.

You can also make your own EHT fuse. You need to get some old ceramic sand filled cartridge fuses, a length of fuse wire of appropriate rating, a glass or ceramic tube 3-4 inches long and 1/4-3/8 inch diametre, e.g from a glassblower supplier. Fabricate some end caps, fix the fuse wire in the middle of the tube and fill it with sand removerd from the cartridge fuses. (Don't use gunpowder from shotgun gartridges).

The sand absorbs the energy from the fuse rupture and surpresses arcing. Don't consider not using sand as you will breifly end up with an arc lamp, then a laundry bill.

Orr wrote an article in QST back in the 60's on cathode driving 4cx type
tubes. He did not suggest triode connection but rather what he called
super cathode drive. It involves feeding some drive to the grid as well
and includes RF feedback ala Collins linears. According to the article,
drive requirements are increased (lower stage gain) and IMD reduced.

Lars (SM4RZW)

According to

ElectricalEngineers Handbook
(Electric Communications and Electronics)
John Wiley and Sons c1950)

Silicon glass lamanate sealing compound
2.4 to 2.85 when Freq < 2kc power factor 0.01 (Note D)
2.4 to 2.82 when Freq = 300 to 2000 kc power factor 0.02 to 0.06 (note
d)

"where possible the ranges of dielectric constant and power factor
include the variations to be expected over the indicated frequency
ranges, although the values up to 2 kc are for 60 cycles or 1 kc and
most of the values in the higher frequency ranges are for 1 mc. For
good insulating materials the dielectric constant does not change
greatly at higher frequencies, but the power factor may rise or fall
considerably...."

Couldn't find any data forthe other...

Greg KB6WKW

For those of you wanting answers as to how and why, I publish the following from the FCC:
****

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20054

In the Matter of }
}
Timothy Harold Hoffman }
Phoenix, Arizona

OFFICIAL NOTICE OF VIOLATION
(corrected copy)
Released: June 26, 1995
By the Compliance and Information Bureau

I. Introduction
1. This is a Notice of Violation issued in accordance with Section 1.89 of the Rules, 47 C.F.R. § 1.89, to Timothy Harold Hoffman for willful violations of sections 301, 303(n), and 333 of the Coomunications Act of 1934, as amended (47 C.F.R. §§301, 303(n), 333) and sections 15.29, 95.413(a)(4), 95.413(a)(6), 95.426(a)) for operating a radio transmitter on amateur radio service frequencies without a valid license, failing to allow inspection of the radio station by authorized fcc personel, willfully and maliciously interfering with radio communications of licnensed stations, and on CB channel 36 transmitting one-way communications, Transmitting material to amuse or entertain.

II. Background

2. On may 14, 1995, Agents from the Commission's Compliance and Information Bureau (CIB), Using
mobile direction finding techniques, detected radio signals on CB channel 36, J3E emmission (lower
sideband), coming from an antenna located at 911 West Highland Avenue, Phoenix, Arizona 85013. The
transmissions consisted of retransmitted signals from an Amateur Radio Service repeater on 147.240
MHz. The following violations were observed from 8:05 until 8:50 pm MST and from 8:55 until 9:15 pm
MST:

Rule Violation Description

47 C.F.R. 95.413(a)(4) Prohibited transmission of one-way communications

47 C.F.R. 95.413(a)(6) Prohibited transmission of any material to amuse or entertain.

3. On May 15, 1995, Agents from the Commissions CIB, Using mobile direction finding
techniques, dtected radio signals being transmitted on 146.340 MHz, F3E emission, coming from an
antenna located at 911 West Highland Avenue, Phoenix, Arizona 85013. The transmissions consisted of
the use of Amateur Radio Service call sign N7ZZT and asking for a new white cane and new eyes, among
other things. Transmissions were observed at 7:44 pm and 8:21 pm MST. At 8:25 pm MST, the FCC
agents attempted to inspect the radio station at 911 West Highland Avenue. The adult male that came
to the door admitted to being Timothy Hoffman and would not allow the agents to inspect the radio
installation. The following Violations were observed this date:

Rule Violated Description

47 U.S.C 301 Transmitting on Amateur Radio Service frequencies without a valid
operator or station license.

47 U.S.C. 333 Willfully and Maliciously interfering with radio communications
of licensed Amateur Radio Service stations.

47 U.S.C 303(n) and Failure to allow station inspection by authorized FCC personel
47 C.F.R. 15.29 and
47 C.F.R. 95.426(a)

III. Discussion

4. Timothy Harold Hoffman was clearly in violation of 47 C.F.R. ¤¤ 15.29, 95.413(a)(4),
95.413(a)(6), and 95.426(a) and in violation of 47 U.S.C. ¤¤ 301, 303(n), and 333.

IV. Ordering Clauses

5. Accordingly, IT IS ORDERED, pursuant to Section 308(b) or the Communications act of 1934, as amended, 47 U.S.C. 308(b) and section 1.89 or the Commission's Rules, 47 C.F.R. 1.89, that Timothy Harold Hoffman submit a written statement concerning the Violations of 47 C.F.R. 15.29, 95.413(a)(4), 95.413(a)(6), and 95.426(a) and of 47 U.S.C. 301, 303(n), and 333 to the following Address:

Federal Communications Commission
P.O. Box 6
Douglas, Arizona 85608-0006

The answer shall contain a statement of action taken to correct the cinditions in violation and
action to preclude recurrence. Each rule section in shown violation shall be addressed seperately.

The staff will use all relevant and material information before it, including the information
disclosed in your reply, to determine what, if any, enforcement action is required to ensure the
current and future Rule compliance. Willful or repeated violation or failure to reply may result in
monetary forfeiture.

A WILLIFULLY FALSE STATEMENT IN RESPONSE TO A REQUEST FOR INFORMATION BY A FEDERAL AGENCY COULD BE
PUNISHABLE BY A FINE OF $10,000 OR IMPRISONMENT FOR 5 YEARS, OR BOTH, UNDER TITLE 18, U.S. CODE
1001.

6. IT IS FURTHER ORDERED that this notice shall be sent by certified mail, return receipt requested, and by regular mail, to Timothy Harold Hoffman, 911 West Highland Avenue, Phoenix,
Arizona 85013.

FEDERAL COMMUNICATIONS COMMISSION

[Signature]
Stephen Y. Tsuya
Engineer in charge
Douglas office

****
END OF FILE.......

****

Since the writing of this notice of violation, Mr. Hoffman has repeatedly violated the terms and
conditions as stated in the above notice. He also jammed emergency communications on the autopatches, falsely reported emergencies, and generally created lots of havoc. He use the Call
N7ZZT on a number of such occasions, as well and the following calls:

AA7KV (Craig Ickes)
K3NPR (invalid call)
K7UZI (Invalid Call)
and others...

His was a pattern of lack of respect for the law. He also used telephone harrassment as a tool to
get what he wanted. This pattern has continued until fairly recently (about 3 weeks before the NAL
was issued). According to the Local Official Observer, numerous tapes and documents were received
regarding this individual and his acctivities. I could not get access to the tapes, or the transcripts of such, as the investigation was still ongoing.

I hope this document answers the many questions you might have regarding this case..

Thank you.

Eric Oyen.

The only way to effectively stop this chain-letter crap is to alert the
ISP from which it originates ... as follows:

(mail/foward the SPAM to "abuse@<abuser's_ISP_domain>" and
"Postmaster@<abuser's_ISP_domain>) with a note like this:

Dear Netcom (chage ISP name as appropriate) System Administrator:

Please deal with this jerk who is SPAMing the net from one of your
sites. (assuming the address is not forged)

I forwarded a similar SPAM to "abuse" and "postmaster" at
PSInet/Interramp, and got a prompt response that the user's account had
been terminated.

I hope I will get the same sort of reaction from your organization.
This stuff has got to stop and the only way is for ISPs to act
responsibly by not allowing their users to spew this stuff to the
newsgroups and/or as unsolicited e-mail to hundreds(thousands) of
unwilling recipients.

Thanks in advance for your attention to this matter,
Carl Stevenson

I in fact tried that, and had a wonderful response from some local electronics firms with gobs of old junk, ripe for stripping, that they didn't want to have to haul away.

And thanks to those with their generous offers! I now have enough homebrew parts coming (or already here) to build just about anything I could want.

Nice bunch of folks here!

I suspect you are replying to AA1A's inquiry regarding a stable lowfer frequency. 166.66666.... has been tried for years and in fact the US Navy used it for a link between San Diego and San Francisco (which clobbered our efforts!) Most unfortunately, SOMETHING tends produce a signal on that frequency almost continually. I would suppose the great number of one megahertz signals floating around eventually would produce a divide by six signal in some strange fashion---BUT the signal is there! Cliff K7RR

Hey Dave....The rating on a resistor is continous. I would put in a regular 50 (or 100 watt) resistor. It will do the job and run cool. If you have an arc over for a short time the resistor eill not "fuse". If the plate supply is over current for very lonf the plate supply fuse should go.

Lars,

There are a lot of different formulations of both materials, so it's likely to vary a lot from one manufacturer or formulation to another. Also, the dielectric constants are likely to change with frequency. I suggest contacting the manufacturer of the particular material to be used. Alternatively, you might try making a capacitor with the material as a dielectric, measuring the capacitance at the frequency of interest, and calculating the dielectric constant from that.

Does the dielectric constant of a material change with frequency? Please fill me in on this, I always thought the dielectric constant was a fixed value independent of frequency. What about the impedance of microwave strip line filters and transmission lines (etched on printed circuit boards), they don't change impedance when the frequency changes and the formula for calculating impedance for strip lines only uses the copper thickness, strip width and dielectric constant of the circuit board material as variables to calculate the impedance of the stip line independent of frequency.

Read the headers to double-check this. E-mail address can be faked fairly
easily (no I'm *not* saying how), but "X-NNTP-Posting-Host" (I think) will
indicate the machine from which the message was really posted, and I suspect
that that's rather more difficult to fake.

Gudday fellow Home Brewers..

My best shot so far for accurate frequency calibration is as follows:

A 5mhz James Knight Proportional Oven Oscillator divided down to 100khz and then compared on the scope with Nantucket Loran 'C' via a TRF receiver does better than .001 PPM with just manual control. This will be much more than needed for LOWFER transmitter frequency calibration. It also lets me tweek the 10ghz brick to within a couple hundred cycles at 10ghz..
I found that by varying the DC on the tuning cap inside the oven and isolating by a 68k resistor then varied from 0 to 28 VDC swings the 5mhz sig by 4 hertz.. This is via a 10 turn precision pot. I never need to turn the pot. more than a quarter turn now to be well within .001ppm..

What are you using??

The TRF receiver is a converted Navy RAK with J-Fets at each tube base.. works fine..

Couldn't see an email address,callsign etc. so I'm unsure whether
you're in USA or Europe!!
In Europe,most ATV is on 24Cms & 10GHz bands using FM Video
modulation,almost the same as used by analogue satellite receivers.
Indeed,most people's receive setup uses TVRO parts.
IN USA,they're "behind the times" in that most ATV uses AM Video
(often on 70Cms band which uses a lot of the available bandwidth).
I know that HRO (Ham Radio Outlet) in USA lists some ATV gear.
There's also an outfit called "ATVQ" who were at Dayton hamfest
when I attended 3 years ago.They had European & USA books on
ATV.
There must also be a national organisation for ATV in the USA.
OTOH,if you're in Europe,give an idea of location or callsign &
I'll respond with where to get info & equipment in Europe.

Quite a few materials change dielectric constant with frequency. The better materials change very, very little. The change generally isn't large.

Strip lines are transmission lines which are embedded in a dielectric and have ground planes on both sides. These change impedance only to the extent that the dielectric constant of the material changes. Microstrip lines are lines typically etched on a circuit board with a ground plane on a lower layer. These change both characteristic impedance and propagation velocity with frequency. This is because the fields are more concentrated in the dielectric right under the line at high frequencies, and spread out more through the air (which has a lower dielectric constant) at low frequencies. Consequently, the propagation velocity gets slower and the characteristic impedance gets lower as frequency increases. Most of the formulas are for the high-frequency limit. Look through the IEEE publications for references under the topic of "dispersion".

Haven't you noticed that most all auto radios have am stereo? Both of
our cars have them and I have one for my bench radio that's at least
10 years old. Works fine on the few am stereo stations here.

1051. Improved AM stereo mod for your AM/FM stereo tuner, using SRF42

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-09 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDxFv48.C66@netcom.com>
Source record: 102581
Cross-posted to: rec.radio.shortwave,rec.audio.misc,rec.radio.amateur.homebrew

Found an improvement on this AM stereo mod I posted a few weeks ago.
Namely, better fidelity and less distortion by raising the SRF42
circuit supply from 3V to 5V.

Also note you can get a SRF42 at radio shack, ask for catalog number 12-127
(look at page 61 of the '97 catalog). And be sure to look for astonished
looks on the sales droids faces, when they see it there!

AM STEREO modification of digital AM/FM stereo receivers, using a Sony
SRF42 AM stereo walkman radio chassis

You probably have a stereo FM/ mono AM receiver for your home
stereo system. And it probably is a PLL digitally tuned radio,
maybe even tunes up to 1700KHz. But still mono. It's nearly
impossible to find an AM stereo set, the only one you can hope to
find is a portable, a Sony SRF42. But it's analog tuned, but it is
possible to use the innards of this Sony to demodulate AM stereo
signals tuned by your PLL digital mono set's front end. Idea
is to disable the Sony's front end, and feed the IF (intermediate
frequency) from the PLL digital circuit to the IF amp section of
the Sony. And take the left and right outputs and substitute
those in your reciever for the mono AM signal.

This is not a project for beginners, you'll need some experience
with radio circuits and fine soldering.

Before you tear into the SRF42, tear into your receiver, and look
for the AM circuitry. Probably a chip. Helps if you have the
service manual. Look for a small squarish plastic part, probably
colored orange. Hopefully it has a marking like "450". Other
shapes these filters come in are a rounded brown 3 leaded thing,
marked "450" (AM) or "107" (FM). The IF frequency of the AM
section needs to be 450 KHz, because that's the frequency used in
the SRF42. Other IF freqs used are 455KHz, which is too much
of a mismatch for the below to work.

Open up the Sony SRF42. First, remove the volume control knob (pulls
out). No need to remove the tuning knob, and don't try to remove
the on=off switch knob. unscrew three screws, and the front comes
off. Unsolder the battery connections to then be able to remove
the radio's circuit board. You'll see a plastic gear that controls
the tuning capacitors. replace the volume control knob on the
volume control shaft (so you can vary the output level later).
Now for the interesting part: connect a jumper wire across the
AM local oscillator coil, located next to tuning cap trimmer CT4.

Jumper goes from ground to the pad connecting the coil to the
tuning cap. This disables the Sony's front end.

Now connect a small cap (about 0.01 uF ceramic) to the SRF 42 at
this point: Look for pin 12 of IC1, and follow the pad to R26,
the point you want to connect the cap to is the pad on the other
side of R26 away from the IC1. Keep the leads short on the cap.
Connect a length of shielded wire to the free end of the cap, and
the shield connects to a 0.1uF cap, and that connects to a local
ground (look for the connection of the metal shield of a nearby
IF transformer). Purpose of this cap is to provide an RF ground,
but to block DC and audio frequencies.

**** Update, distortion improvement ****
I found that the SRF42 offers beter fidelity and less distortion
if operated at 5V DC. Normal supply voltage is 3V. The extra
voltage appears to offer more dynamic range on the audio. I don't
know how close I'm pushing overvoltage, though, so do this at
your own risk!

At the other end of the shielded cable connect a 1K resistor to the
center conductor. Now you will need to do a bit of poking around
in your reciever with the power on, and power up the SRF42 and listen
with headphones (you should only hear some hiss, no stations). Tune
a local AM stereo station on your reciever (though your reciever only
gets it in mono now). Look around the above mentioned IF frequency
modules you checked before you took the SRF42 apart. Now tune the
volume on the reciever down, and the SRF42 up some, and start poking
around with the 1K resistor attached to the cable. Oh yeah, connect
the minus power terminal of the SRF42 to the reciever's ground. Poke
near modules marked "450" and you should soon hear the SRF42 playing
the station you tuned the reciever to. Try a number of locations
and note which sounds better (less distortion, a reasonable amount
of high audio freqs, and when you select a point, check a few other
stations. When I selected a point to tap, I connected a 1K resistor
to the top of a 1K trimpot, the other end grounded, and the wiper
feeding the cable. Then I could tweak the level for a reasonable
signal, decent signal to hiss, vs distortion if the signal gets too
strong. If the point you selected has a DC bias on it, use a 0.01
cap in series with the 1K resistor to avoid loading the DC.

To power the SRF42 "chassis", I used a 5V regulator chip. See above
note on overvoltaging hazards that may exist when running 3V circuits
at 5V. Though analog circuits tend to be more forgiving of overvoltage
than digital stuff. Proceed at your own risk on this.

To cut some of the high frequency audio hiss and noise, I connected
0.015 uF caps to ground, and the other end of one to a pad connected
to IC5 pin 2 and the other cap to pin 4. A more convenient attachment
points are located just under the volume control. Not the pot
connections themselves, but look for 2 pads closer to the board edge
that lead to the IC5 pins 2 and 4.

I just connected the headphone jack to the audio amp, and used the SRF42 volume control to set a reasonable and undistorted signal level.

1052. Converting a CB radio

GS> The VT-25A tube is listed as a "10Y" or "10 Special" in the
GS> literature. Does anyone know "Y" it is "Special"? Is it just a
GS> ruggedized 10?

Hi Gordon, the 10 and 10Y differences is in the plate to filament capacitance. 10 = 4 Pfd and 10Y = 3 Pfd. The 10 = 6 mHz had a lower maximum frequency to the 10Y which = 8 mHz. If you find a Raytheon RK10, it had a guaranteed frequency of 60 mHz which at that time was in the UHF band. The 10, 10Y and RK10 all are equal in power requirements and output specs are identical. The 10 tube was also used in receivers and had specs for that use and can be located in the early ARRL Handbooks.

: Looking for details on homebrewing a SINAD meter.
: Means of display is not important. I'm mainly interested
: in the method of sampling so I can process it with a microcontroller.

Here is a somewhat simplified explanation. A SINAD meter is essentially a type of audio distortion meter. You also need an RF signal generator and a precise audio frequency source to modulate the RF (usually 1 KHz). The SINAD meter is connected across the audio output of of the receiver. The modulated RF is fed into the receiver's front end. The SINAD meter has a sharp notch filter to cut the 1 KHz modulated signal. The receiver's IF cans are adjusted to minimize reading on the SINAD meter (i.e. minimize noise).

SINAD measurement approximates signal to noise ratio as (signal + noise) / noise. So if you divide the signal sampled just before the notch filter by a sample of the signal just after the notch filter, you will have a handle on the signal to noise ratio. Generally, you use a very weak RF signal when doing SINAD measurements so that internal RX noise is a major component of the audio signal.

A commercial SINAD meter will perhaps use analog multipliers, agc, and have calibration scale. But for tweaking the cans of an RX there is no need for any calibration. If you wish to do SINAD digitally, you need to implement a digital notch filter. It would make a good DSP project. Any good book on FM communications will have a detailed description of SINAD.

Here is a way to quickly, easily generate large streams of cash in relatively little time with very little investment. It's worked for others and unlike most get-rich-quick schemes, it will work for you. Does a $7,000 return on a $7 investment sound like a worthwhile opportunity? $17,000? $27,000? If you could use that type of money, and you can spare seven bucks - five $1 bills, envelopes and postage - read on. I know you're skeptical, and so was I at first, but I ask you to please read on and get all the facts before you write off this incredible, legal business opportunity. Someone else wrote the instructions below, but they did such a good job I figured "why mess around with them?" They might seem long-winded, but please bear with them - you *will* thank yourself later... if you're paying an hourly connection fee, it probably doesn't matter since you'll soon be swimming in cash anyway. But if it's really a concern, download this article to your computer or print it out and read it offline. You will NOT be sorry! Here are the instructions:

****
*

!!!HONESTY IS WHAT MAKES THIS PLAN WORK!!!

****
*
I wrote a small note to send with the dollar saying "please add my name to your list." I then took the first name on the list off and moved the
rest of the names up one slot. Then I added my name in the number 5 slot of the list (The placing your name on the list is where you make money). I then took the new list of names, which now included my own, and E-Mailed it to every BBS operator in Fidonet, which is a group of BBS operators across the world. I figured that was a good way to get it to a lot of people fast. I then sat and waited for the money to come in. I was expecting to maybe make, at the most $500 to $600 dollars, or at least somewhere in that area.

The secret from my wife was out after about 2 to 3 weeks. It became very hard to keep the secret any longer from her, because of the return addresses. She was wanting to know who, what and why there people from all over the world where sending me a dollar bill. I then explained it to her and she could not believe it. The mail continued to come in every day. My mail carrier even questioned me once or twice. it was a feeling beyond belief. I guess that you want to know how much I made now? Well, I did not reach $35,000, but I did bring

in $14,684. I just could not believe that it worked this well.

The first thing I did was pay off mine and my wife's car. It felt so good calling the bank and asking for a payoff. I then took the rest of the money and paid off as many of my credit cards as I could. Now after 1 year, I am ready to do it again. This time my spouse suggested USEGROUPS on the Internet, and I believe that it should work better than before. I think that someone could hit that $35,000 mark, but I do not know that yet. It all really depends on you, the individual. You have to follow through and re-post this message everywhere you can put it. the more people you get it to the better the response you will get. It is just too easy to pass up this money making system!

I will say this much about this system, it works! I got hold of this list after it had already been all over my home town. I have talked with everyone of the below list, and they said that they started out thinking that it would not work. Most of them made more than I did on the first go around. I am not yet really sure who started this thing or really where, but THANKS!"

!!A LOOK AT THE REASONS YOU NEED TO DO THIS!!

Let's look at the reasons you need to do this. First of all it only costs less than $7 - 5 $1 bills, 5 $0.32 stamps, and 5 envelopes that you need to mail to the 5 names on the list. Then simply re-post the message and list, with your name on it, to all the USEGROUPS and public BBS's you can. Then just sit back, relax, and enjoy receiving mail in your mailbox - mail with dollar bills in every envelope! Everybody has $5 dollars to put in something that will make them $10,000 to $15,000 dollars in about 3-6 weeks. Ask yourself this simple question, "Where can I get $5?" Take lunch to work one day, drink water instead of pop or tea five times, hold off on those lottery tickets, and put $5 dollars in this MONEY MAKING SYSTEM NOW! It is really hard to lose.

Follow these instructions step-by-step if you are ready to make some money. You might want to make a printout of these steps to make them easier to follow.

1. On a blank piece of paper write the following message:

"Please add my name to your list".
** YOUR NAME AND ADDRESS **

You will be paying for a legitimate service and making this money system completely legal. You will not be just sending a dollar to someone, but paying for the legitimate service of adding your name to their list. Make sure to also write down your name and address on this piece of paper. I assure you once again that this is completely legal!

2. Fold your piece of paper around the dollar bill, (NO CHECKS OR MONEY ORDERS), and put both in the envelope. Address an envelope to all 5 of the people on the list. You will find that list at the end of this message.

3. Now, here is where you make your money. Look at your list of 5 people. Remove the name in slot number 1, and move all the other names up 1 slot. For instance, move the name in slot number 2 up to slot number 1. The name in slot number 3 then moves up to slot number 2. The name in slot number 4 should then be moved up to slot number 3, then finally the name in slot number 5 up to slot number 4. Then put you name and complete mailing address in slot number 5.

4. Now, upload this updated file, with your name in slot number 5, to as many USEGROUPS and BBS conference areas and file areas as you can. Remember the more people that get the message to the better the response will be for you, and the other people on the list. Give the message a real eye catching name so it will catch someone's eye. Some examples are: "Need some extra money?", "Need some money quick?", "A way to pay off your bills fast!!!", or "Money!". Set a goal on how much money you want to make and keep these numbers in mind at all times. With this goal in mind, you will get a good figure of how many people must read the message and then respond. You can make it easier for people to receive your message in USEGROUPS by UUE encoding the file when you are uploading it. That way people can download it to their hard drive or a floppy. Don't alter the file type, leave it as a MS-DOS Text file. The best way to test the file is to open the file using Notepad in windows to make sure the margins look right. You should make sure that the viewing person does not have to slide the screens back and forth to read the message. One other thing about the list of names, you should not try any funny editing of the list of names.
You should add only your name and no others to the list. If you want a friend to do it with you give them a copy of your edited list, with your name on it, so you can make a dollar for yourself.

5. If you need help uploading your file, ask someone on the system you are trying to upload to. Somebody will always help you with the matter. When you upload it as a file on a BBS by sure to give the file an eye catching name like: "CASH.TXT", or "MONEY.TXT".

6. After you do all the above steps sit back and wait for the money to come in. Expect to see some money start in about 2 weeks. When week 3-4 rolls around, the money will really start coming. It is more than just a normal feeling to see all the money that you will receive.

7. Now you pay off all your debts, and then go and buy something that you have always wanted or maybe something that you have always wanted to get someone else. After that, just enjoy life!

8. When you have spent all of that money, simply start posting the same message again. Post it in the old places, and maybe some new

places. Don't just delete this file after the first time, because you
can reuse it time and time again in the same
way you did the first time.

The list of names are below.

There are several on the internet, search using morse as the
key word. But the best i have found is Morse Academy. I don't know
if it has a windows version, but the DOS has gotten me through
5 WPM and I'm making a strong run for 13.

The best practice is to copy off a actual transmission though.

1057. Need schemo for R174 military surplus rx.

Here's a weird one (for most folks... for me it's typical):

I seem to have misplaced my two copies of the schematic
for my R174 general coverage military surplus receiver. This
beast was made by Emerson Radio around the 1950s. It covers
1.5 through 18 MHz and uses 1.5vDC tubes. The tubes are
(in varying quanties) 1L5, 1R5, 1U5 and 3V4. IF=455 kHz.
Big green box with a monster two-gearing dial and 9 "channel"
buttons that are really little screw-stops around the inside
channel of the outter knob's ring.

Anyone got a copy of the schemo for this monster? I'll
pay for copying cost and mailing. (It sure beats having
to take the cover off the radio every time I wanna check
out how it's working.)

Dear Dave,

Sorry, there have been no touch-up paint kits for the Kenwood radios.
The casings are powder coated when painted. I will forward your comments
to our Product Planners. There can be a slight difference in color even
with the new radios from batch to batch.

Daaah, what. I've never seen one yet. My truck dosn't
have one, none of the other cars I've seen have one, not
one aftermarket unit in Crutchfield has one.

Source record: 102591

Hi there,

this might not be directly about this thread (which is very interesting
for a 'post-tube-aera ham'):

I am about to build two 4XC250 based linears for 2m and 70cm. I have
found several descriptions in old ARRL and RSGB VHF/UHF manuals which
might be a way to go (one uses water pipes as transmission line in a 2m
push pull design).
But maybe some of You 'tubers' knows about more recent designs published
somewhere?
I don't think, that tube linear design has changed much since the time
these books were published, but some parts may be hard to find nowadays.
I have 4 4XC250FG tubes I bought at the HAMRADIO in Friedrichshafen some
two years ago. They are B types with 26.5V filament voltage.

Thanks in advance for any help.

Source record: 102592

Steven Kerns (skerns@mail.talon.net) wrote:
: Does the dielectric constant of a material change with frequency? Please
: fill me in on this, I always thought the dielectric constant was a fixed
: value independent of frequency. What about the impedance of microwave strip
: line filters and transmission lines (etched on printed circuit boards), they
: don't change impedance when the frequency changes and the formula for
: calculating impedance for strip lines only uses the copper thickness, strip
: width and dielectric constant of the circuit board material as variables to
: calculate the impedance of the stip line independent of frequency.

I think Roy Lewallen, W7EL, already provided a pretty good answer to this.
I'll add that typically materials with high dielectric constants get them
from having molecular dipoles that are moved in the electric field. As
the frequency increases, these dipoles have a harder time responding to the
field, so their effect decreases and the dielectric constant decreases.
For example, the dielectric constant of water is listed in Sams' "Reference
Data for Engineers" as follows:

freq	dielectric const.
1MHz	78.2
100MHz	78
3GHz	76.7
25GHz	34

The dissipation factor goes up correspondingly, as the dielectric constant
goes down. The effect isn't limited to liquids. Here's Nylon, for
instance. Though not as dramatic, it's quite significant.

freq	dielectric const.
60Hz	3.7
1kHz	3.50
1MHz	3.14
100MHz	3.0
3GHz	2.84
25GHz	2.73

Dielectrics generally considered "good" at RF tend to have very stable
dielectric constants with frequency: Teflon, polyethylene, polystyrene.

Here are some relevant provisions of Part 15:

> Sec. 15.233 Operation within the bands 46.60-46.98 MHz and
> 49.66-50.0 MHz.
>
> (a) The provisions shown in this section are restricted to
> cordless telephones.
> (b) An intentional radiator used as part of a cordless telephone
> system shall operate on any frequency within 10 kHz of one or more
> of the following frequency pairs:
>
> ...
>
> (c) The field strength of the fundamental emission shall not
> exceed 10,000 microvolts/meter at 3 meters. The emission limit in
> this paragraph is based on measurement instrumentation employing an
> average detector. The provisions in Sec. 15.35 for limiting peak
> emissions apply.

So, if your replacement or supplemental antenna exceeds these standards, then you have a problem. My layperson's understanding is that if you repair or modify such equipment, *you*, rather than the manufacturer, become responsible for it! They really expect you to know what you're doing.

By contrast, the general provisions for that band are less restrictive and recognize homebrew devices:

> Sec. 15.235 Operation within the band 49.82-49.90 MHz.
>
> (a) The field strength of any emission within this band shall not
> exceed 10,000 microvolts/meter at 3 meters. The emission limit in
> this paragraph is based on measurement instrumentation employing an
> average detector. The provisions in Sec. 15.35 for limiting peak
> emissions apply.
> (b) The field strength of any emissions appearing between the
> band edges and up to 10 kHz above and below the band edges shall be
> attenuated at least 26 dB below the level of the unmodulated
> carrier or to the general limits in Sec. 15.209, whichever permits
> the higher emission levels. The field strength of any emissions
> removed by more than 10 kHz from the band edges shall not exceed
> the general radiated emission limits in Sec. 15.209. All signals
> exceeding 20 microvolts/meter at 3 meters shall be reported in the
> application for certification.

> (c) For a home-built intentional radiator, as defined in Sec.
> 15.23(a), operating within the band 49.82-49.90 MHz, the following
> standards may be employed:
> (1) The RF carrier and modulation products shall be maintained
> within the band 49.82-49.90 MHz.
> (2) The total input power to the device measured at the battery
> or the power line terminals shall not exceed 100 milliwatts under
> any condition of modulation.
> (3) The antenna shall be a single element, one meter or less in
> length, permanently mounted on the enclosure containing the device.
> (4) Emissions outside of this band shall be attenuated at least
> 20 dB below the level of the unmodulated carrier.
> (5) The regulations contained in Sec. 15.23 of this part apply to
> intentional radiators constructed under the provisions of this
> paragraph.
> (d) Cordless telephones are not permitted to operate under the
> provisions of this section.

and as an individual, the standards are much less rigorous:

> Sec. 15.23 Home-built devices.
>
> (a) Equipment authorization is not required for devices that are
> not marketed, are not constructed from a kit, and are built in
> quantities of five or less for personal use.
> (b) It is recognized that the individual builder of home-built
> equipment may not possess the means to perform the measurements for
> determining compliance with the regulations. In this case, the
> builder is expected to employ good engineering practices to meet
> the specified technical standards to the greatest extent
> practicable. The provisions of Sec. 15.5 apply to this equipment.

So ordinary folks can do interesting things without learning CW, such
as:

> Sec. 15.217 Operation in the band 160-190 kHz.
>
> (a) The total input power to the final radio frequency stage
> (exclusive of filament or heater power) shall not exceed one watt.
> (b) The total length of the transmission line, antenna, and
> ground lead (if used) shall not exceed 15 meters.
> (c) All emissions below 160 kHz or above 190 kHz shall be
> attenuated at least 20 dB below the level of the unmodulated
> carrier. Determination of compliance with the 20 dB attenuation
> specification may be based on measurements at the intentional
> radiator's antenna output terminal unless the intentional radiator
> uses a permanently attached antenna, in which case compliance shall
> be demonstrated by measuring the radiated emissions.

although, being able to send and receive CW might be be essential to use
that band effectively. But you aren't required to be able to copy CW by
ear (or flashing light if you're deaf) in order to use it...

Where the FCC expects ordinary folks to operate, they provide less technically demanding standards for compliance that parallel the field strength measurements that most of us are not able to make.

I don't know why I didn't think of it before, but instead of the crystal and two capacitors, my PIC-based keyer could use a single ceramic resonator. Now though, I may have to add a part...

Could someone tell me if there's a "standard" specification for the voltage across an open Morse key/paddle, or how much current the contacts are expected to handle?

Specifically, I need to know if 5 Volts open-circuit is typically enough, and whether sinking 25 mA closed-circuit is sufficient. If not, I'd have to add a FET to my dinky keyer. Oh well, I was thinking I should add a cap across the PIC's power pins anyway.

Rick Miller (kb9obn) rdmiller@execpc.com

1065. Any homebrew uses for scanner crystals?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-09 00:00:00 UTC
From: mjsilva@ix.netcom.com

Source record: 102595

I've ended up with a few bags of scanner crystals in the 150-160 and 450-460 MHz range, and I'm trying to think of something useful to to with them (other than to shim the leg of my chair). Since I've got a number of identical units the thought of filters naturally occurred, but (a) the fundamental frequency (~16 MHz) is higher than I think of when I think of filters, and (b) I don't know how well overtone crystals would work in a filter (in their fundamental mode). Any ideas?

Another question about overtone crystals: can they be operated at any odd overtone up to their designed frequency just by tuning the oscillator tank, or is there something that only allows an Nth overtone crystal to work at the N overtone? I know the frequencies won't be exact submultiples, but there might be a useful frequency in there somewhere.

Finally, is there a typical "N" for an Nth overtone crystal in the two above ranges? I measured one of the 460 crystals and got a fundamental about 27.6 times lower than the marked freq. I gathered from this that it's either a 7th overtone meant to be quadrupled or a 9th overtone meant to be tripled.

>That's fer sure...

I just took apart my first microwave oven. Despite the horribly banged-up door and timer, the power stuff inside, including a nice 110 V -> 3.3 V & 1850 V transformer all looked brand new, and tested out ok with the inductance meter. It also had an HV diode, a .77 uF 2100 VAC cap, and a hefty blower. (Um, and a magnetron.) Not bad for something in a ditch by the side of the road!

I don't know the power rating of the transformer, but the oven was fused at 10 amps (120 V) so it'll probably run a kilowatt input amp no sweat.

Here's to abandoned microwave ovens!

Well, if you're keying an old-time tube transmitter, you could have
+150V or more on the key during key-up (cathode keying). If it's a
grid-block-keyed system, it might be -150V (if memory serves, the
once-popular Heath HW-101/SB-102 had this kind of voltages). You can't
just put a zener across the keyer to clamp this, either, since that will
effectively turn the rig on all the time.

From: hjohnson@pluto.njcc.com
Message-ID: <4H4DouoWWZZ7079yn@pluto.njcc.com>
Source record: 102598

I've just built a 400 MHz "Slipper dipper" grid dip meter as per the
construction article in the ARRL Handbook of the early 1980's, to tune
up a 408 MHz collinear array I've built (yes, 408 MHz, radio astronomy).
It apparently does not oscillate: my 100 MHz oscilloscope has NO indication
(even at 400 MHz it has some response); the sensing ammeter does not
register any output; and my cable-ready TV does not respond on any channels.
It is built very close to the specifications given EXCEPT:
different transistor (new UHF\VHF NPN transistor used)
MAYBE different PCB material (unclear if FR-4 or G-10 specified,
different versions of the article contradictory, I used FR-4)
slightly longer brass and copper tubing (by .5 inch)
used Teflon for mounting tubing
used lock washers to hold tubing and to make contact to brass rod

I'd like to find someone in the greater NJ/PA/NY area with 400 MHz
equipment to help me get this working. Or, who has the equipment to tune
AND match this antenna to our LNA's. I don't want to send this unit
cross country for obvious reasons. Though I'm an electrical engineer,
I'm not an RF engineer by profession so I may have missed a trick somewhere
here.

And at 500 THz - light - the "dielectric constant" gets renamed
"refractive index" (maybe there's an extra square root, though) and for
water it's only 1.33 at optical frequency. (Techinically, permeability
matters too, but it's negligible for water.)

There are few things with refractive index as LOW as that of water up at
optical frequencies. Most minerals and most organic materials are higher.
Diamond has a very high index, 2.42. Which isn't much to an RF engineer!

Hi!

Can someone tell me what open-circuit voltage and closed-circuit current the device attatched to the "key" input of a rig is supposed to be able to handle? If 5 Volts and 25 mA is sufficient, I'll be a happy camper!

Otherwise, I'll have to use a FET I guess.

Typical microwave ovens are only rated at about 600-700 W. Not sure if that is DC input or RF output, though. Of course, it is quasi-cw!

You have the makings of one FINE bugzapper there!

On a serious note, you are probably looking at the makings of a fine
600 -800 watt amp assuming you can find and afford the proper tubes
and associated variable caps.

Be very careful, though, when playing with your new-found toys. 3 KV
AC is definitely in the fatal range. Louisiana used to pump 2.4 KV
into the electric chair...

Steve:

Just one further thought. As a kid (now 50) I even collected my own
galena and made that work. We didn't even have Schottky diodes in those
days. a 1N34 was high tech! White (grey) razor blades also work as does
pyrite and powdered (rusty) iron filings. Galena is best. I note you
are in Ma. I know you can collect galena and pyrite at the Sterling
Hill Museum near Franklin, NJ. I had a lot of fun as a kid trying to

find the "most sensitive" spot on the small crystal. I even managed HCJB - Quito, Equador - on my galena crystal radio one night from central Michigan! Have fun - combine a mineralogy/mining trip with building a cheap radio!

THE WESTERN CONNECTICUT HAMFEST
Sponsored by the Candlewood Amateur Radio Association

Just 14 miles from the NY/CT State line!

Sunday, Sept. 15, 1996 0900-1400
Edmond Town Hall Route 6, Newtown, CT
Tables inside Tailgating outside
ARRL Sanctioned Handicapped Access
Door Prizes Ample Parking
Gourmet Fare Rain or shine

Talk-in 147.12/.72 PL 141.3

General admission $4.00 at the door (what a deal!)

Tailgating $6.00, inside table reservations $10.00 each, (both
include 1 admission), mail to:
Candlewood Amateur Radio Association, PO BOX 3441, Danbury CT 06813

For more info, phone (203) 790 7041 or (203) 438 6782.

Hope to see you all there.

>What are you using??

I have some surplus 12V precision 16.384 MHz OCXOs that are adjustable
by external pot +-0.5ppm and stable to 0.001 after warm up. These can be
devided by 2^12 to 4kHZ or 2^14 to 1kHZ. I can supply them precalibrated
to +-0.2ppm, ageing is very good so calibration will last for a year or
so. Let me know if any one is interested.

1079. DSP software for sound card?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-09 00:00:00 UTC
From: hugo@infobahnos.com
Message-ID: <51189o$lo9@news1.total.net>
Source record: 102609

Hi everyone,

I 'think' I have seen somewhere, on this or other radio n.g., there are sound card softwares (DOS or WIN 3.X) that permit to implement some kind of DSP filtering of the audio spectrum, requiring only a cable connection between rcver headset's output and card mike's input.

Or was it just a daydream? Any sharewares, demos, beta release, commercial products out there?

Anyone to wake me up?

Thanks,

H. C.

Just knock out the two shunts in the magnetic circuit to remove the current limiting on the microwave transformer. The shunts are the two metal blocks that are between the primary and secondary windings. These work in the same way that the shunts do in a neon-sign transformer to make a current-limited transformer.

Well, actually there are no marking on the panels of our sets that say
AM Stereo until you tune in to a station that is transmitting am stereo
and then it lights up. The first car that I had it in was a 86 Plymouth
Reliant and then a 88 Dodge. Look for one of those in the junk yards.
The problem now is that there are only a few stations still using
am stereo, and in our area there were only two. Now one.
It may be nobody is making the am stereo radios anymore, I can't say
for
sure, our newest car is a 91. Call a local am station and ask if they
know
of any am stereo stations in your area. Good luck.

Ford premium radios with cassette and/or CD players all have
AM stereo. Also, while in Japan, I found that AM stereo is
really popular due to difficult FM propagation (due to
Japan's mountainous terrain). Almost all stations in
Japan use AM stereo. There's an excellent
AM Stereo/FM/Japan TV pocket radio made
by AIWA sold in Japan. It tunes 76-108 MHz and
has selectable 9 kHz, 10 kHz AM band spacing.
I have one and it gives superb reception of AM
stereo. They go for about $65.00 in Japan. It
would be a great idea if Grove or someone would
import a bunch of these things. AM Stereo or not,
it's a great receiver! AIWA does market a similar
unit here in the U.S. but it lacks AM Stereo,
the Japanese FM band, and TV band.

1093. low power 300MHz transmitter

Hello,

For a security application, we're looking for a simple swept frequency (i.e. varactor tuned) oscilator/transmitter design for the 300-400MHz range. Power output should be about 500mW. Coupling to an antenna (such as a simple rod) is also necessary. Frequency stability isn't mandatory and a simple design (even single power transistor) is preffered. Fixed frequency (manual tuning) designs are also welcome. Can anybody point us to a simple design (and save us some of the hassle when designing from scratch...:-)

thanks and best regards,
Inno

But you will find that the regulation of the transformer is very poor.
It is designed to be that way for current limiting. The diodes and
blower are useful.

>GLOWBUGS lists (Glowbugs is devoted to homebrewing tube gear).

I'm not so sure of that. Between Hamtronics, Ramsey, Tentec, the late unlamented VHF Engineering, Down East Microwave, etc, and conversion of commercial surplus, I'd suggest that FM is the most popular for those who build or modify. And a good deal of that gets pressed into digital service. Note that this isn't scratch construction for the most part, but rather depends on kits or commercial surplus assemblies for the parts and basic design. However, a look at _Microwave Update_ or one of the Proceedings issues shows considerable at home scratch construction of this sort of equipment too. (And most of the kits aren't of Heathkit quality so they require considerable skills by the builder beyond simply following instructions and knowing how to solder in order to get them operational. Thus I'd tend to lump them under the banner of homebrew.)

I know the sales figures for the GRAPES 29 MHz quadrature transceiver kit (several thousand units), and I have a fair guess for some of the others. Discounting commercial surplus conversion for the moment, I'd suggest we're looking at something on the order of 30,000 to 70,000 non-CW units which have been shipped. Add in conversion of commercial surplus and you're looking at well over 200,000 units (conversion sometimes only requires changing the crystal and repeaking, which shouldn't qualify here, but often it requires fairly extensive changes which IMHO could fall into the category we're discussing). Note for the most part we're talking about both transmitters and receivers here, not just transmitters, IE complete working stations.

If we also include the CB->10m conversions (including conversion of AM rigs to FM), we're looking at several thousand more non-CW home projects. And we have ringers like Campbell's T2 and R2. They're quadrature units. They can be used for CW, but they also work fine for SSB or digital (which is how I'm using mine). I have no idea how many kits Kanga has sold, or how many were built directly from the QST articles. I built mine from the articles, and modified them extensively in the process by replacing the analog audio phasing section with a DSP. I use them for QPSK experiments, but they would have worked for that without the DSP (just not as well). I know several others doing similar things with them, and some folks using them as SSB exciters (followed by a homebrew amp) and receivers.

Most ATV transmitters (and receiving converters) have been homebuilt. They've either been kits or scratch built for high level modulated VSB, and for FM they have been mostly kits with only a few scratch built (pity, the FM units are easier to scratch build than the VSB units, and offer better performance). Of course the total isn't huge in any case since ATV isn't a hugely popular amateur mode.

I'm leaving out what was historically the biggest kit supplier, Heathkit, because I don't think of them in the same way as the others. They are truly just home assembly rather than what we'd consider homebrew because of the extensive instructions and the care with which the units were designed to make them foolproof to assemble by someone with virtually no skills beyond reading and following directions. If they were included, you'd have a large number of respectable SSB transceivers and FM transceivers to add to the total. (I believe the HW-101 was the largest selling amateur kit of all time.)

>Jeff KH2PZ / KH6 (ex WA6QIJ) (exclusively using homebuild CW transmitters)

But the transmitter is only half of the station, and usually the simpler half at that. What about homebuilt receivers? I'd say by far the most popular receiver to build is a simple FM monitoring receiver. It is only one chip today, and can be assembled in an evening, yet it offers remarkably good performance (and you can build a matching one chip FM transmitter to go with it). Even a simple DC CW receiver is usually considerably more time consuming to build, and performance can be poor because of oscillator stability problems, no single signal filtering, and the hum pickup problem. The DC receiver works as well (or as poorly) for SSB or RTTY as it does for CW too (much the same can be said of superhets, depending on the filter chosen).

I don't have much info on sales figures of QRP CW kits, though I suspect most of them sell in the hundreds, not the thousands, and I'm fairly confident the total is below that for the FM units mentioned. Quadrature and SSB kit sales (other than Heathkit) probably lag the CW kits because they are a bit more complex and specialized (but not very much, most of the complexity is in the receivers, and for good performance the CW receiver can't be much simpler than the others).

I've only addressed radios, but if we look at other parts of the station suitable for home construction, we see a lot of activity. TAPR says their TNC kit sales exceeded 20,000, and GLB sold a bunch of their kits too. If we were to include Baycom or Hamcom style modems, the numbers would be huge, but I'll ignore them as too simple to fit this category.

And of course there are amplifiers, antenna tuners, and antennas. They aren't respectors of mode, but many many amateurs build them. Now neither of the latter are rocket science, but it does take a wee bit of skill to get all but the simplest working right. Linear amplifiers are one of the most popular home contruction projects, and one of the most common homebrewed items seen for sale at hamfests. They can be challenging to do properly.

I think you see CW transmitters as the most common because that's all you do, so your vision is a bit myopic on the subject of home constructed equipment (or you may be insisting on a purist definition of homebrew which doesn't admit anything but an original design by the home constructor). If you were active on other modes, you might find that there is quite a bit of building going on for them as well. Probably only at microwave, and for ATV, is homebrew the majority course, but it is alive and well on most of the other modes, not just among CW operators.

For beginners, I think FM offers the best point of entry. The systems are simple (considering both transmitter and receiver), stability is less of a concern, performance can be quite good thanks to the common availability of high integration parts, and the only encoding you need to understand to use them is ordinary speech. There's also the factor that RF gets easier to do as you go up in frequency to where you can use simple striplines printed on circuit board, IE the "no tune" designs, and where you can use unconditionally stable MMIC amplifiers, and where high gain antennas are small and practical to build and install.

You will have to replace the crystals, AND re-tune the transmitter stage coils and the receiver front-end coils (i-f coils should not need to be adjusted, except to peak the alignment due to old age). I assume from your too-brief description that the radios use a pair of crystals for each channel. If this is the case, I wouldn't bother with them. Rocks cost about $10 each, or $20 per frequency, and IMHO that's too much to waste on 10m AM. Save your money and your trouble. If you wanna do a CB-to-Ten conversion, pick up a 40-channel SSB rig at a flea market or pawn shop and convert that. It will be infinitely more useful when it is all said and done.

Source record: 102626

Are you rebuilding a Heath HP-23 series power supply? You are? Well, great... I have the capacitors you need to complete the job:

Sprague 150 uf, 500 WVDC, twist-lock cans, brand new fresh stock (not dried-out leftovers from some old TV shop!). Set of four is $40 plus $3.00 for postage. Nearest caps on the market these days cost $20 to $25 each! Sold in sets of four only! I have TWO sets available, and I may not be able to get any more I know I said this once before, but my supplier managed to locate a few more).

Contact me via email: kc5ng@dlep1.itg.ti.com

Thanks and 73! Dean Hemphill, KC5NG

That depends entirely on the rig. Some can be keyed with TTL levels
and currents, others have open circuit voltages of -150 volts or more,
or key down currents of an ampere or greater. One size does not fit
all. Most modern Japanese radios will work with TTL levels, but consult
the documentation of the particular radio before trying that.

Because a end system reflected it back on internet. Sometimes that happens
when a system is "full" and/ or the software is flawed. I'm not sure if
that was the case here or not.

The same thing happened with that very same system a month ago, it stated
bouncing everything back. Either the operator is a Lid or the software is
incorrect.

This sort of thing is available free for the PSA DSP-based sound cards
like the Cardinal, which I use. I think Echo (who designed the PSA ASIC)
is the only firm making them now, but you might find a second-hand one
going cheap.

Message-ID: <515br1$721@newsbf02.news.aol.com>
Source record: 102633

I'm looking for any info on the Alinco DR-610T. I found the standard red and blue
jumper mods. However, this clipped the red jumper and it did not restore the 800-900MHz Rx. As far as I can tell it only allowed access to the AM Aircraft band. Is there a button combination I need to press to access the extended upper frequencies?
The mod file also mentioned a set of touch pad sequences used to modify the radio when the key-lock mode is in place on the mic. What are they?

I built one of those several years ago and it worked fine. To be sure
that it is oscillating, I suggest that you use a sensitive counter such
as the Startek with a short whip sniffer. I use a Startek with the
bargraph display for tuning many oscillators and multiplier stages.
Works great. Good luck.

Sounds like you're talking about the venerable J-pole antenna which looks something like a cactus, especially the copper pipe variety. :-) There have been many ham mag articles on building J's. I think the last one I saw was in the July or August issue of '73, if you can dig it out from amid the multipage, never-ending diatribe of Wayne Green. The ARRL Handbook and Antenna Handbook also are sources. Hope this helps you.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
September 15th, 1996
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)

1112. Using GPS as accurate frequency reference?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-11 00:00:00 UTC
From: jeffa@ix.netcom.com
Message-ID: <516eba$6f3@dfw-ixnews4.ix.netcom.com>
Source record: 102492

At a recent swapmeet I picked up a couple of old Trimble Navigation GPS receivers. I've been told that these can be used to perform frequency comparisons between an external reference oscillator and *something* from the GPS satellites. Does anyone know what this might be? Can GPS satellites be used as an accurate, stable frequency reference, and if so, what are the principles involved?

These receivers happen to have connectors for an external oscillator (to be used in lieu of the internal oscillator), and there is a display menu that displays both 'delta f/f' and the average of this quantity. I've assumed this is a comparison between the internal (or external) oscillator frequency and something in the GPS signal, but the manual copy that I have is quite unclear regarding this feature. Does anyone out there know what might be going on?

I'd like to use one of these receivers (the one I've been able to repair, that is) to adjust and monitor a frequency standard (I just picked up an HP 106B that also needs repair). I was about to build a WWVB receiver for this purpose when I stumbled across these last weekend. Hopefully they can be used in this application, otherwise, at least I'll have an accurate time reference and I'll always know where my house is!

From: christer.jogenborn@era.ericsson.se
Message-ID: <516fe8$kmp@erinews.ericsson.se>
Source record: 102493

Got a 'ex.linear' transistor final amp. for 144MHz.
On SSB the PA sounds very bad, according to
the guys on the band.
It is a 12VDC two-transistor PA with a gasfet preamp.
MIRAGE rated 160W output, but i'd rather say 125W
at the moment.

I want to get the PA into shape again, and need
some hints on what-to-check, bias, current balance
on the transistors etc..

The orbiting GPS satellites have cesium clocks aboard each one, so they know what time it is. They broadcast this, and your handheld picks up these transmissions. However, the handheld is a different distance from each bird, so the speed-of-light propagation time is different for the signals from the different birds. Your handheld then solves for where it must be located in order to receive these signals with the relative delays that actually occured. There must be as many equations as unknows: If you can receive three birds's signals, you can solve for latitude, longitude, and time. With four birds you can also find your elevation. With more than four, you are in "overdetermined" mode and can take averages of the different solutions, gaining accuracy.

When I say "solve for time," this means to the nearest 100 nS or so, in an absolute sense (and with the fuzzing, "selective availability," turned on, rather better if it's off, which will be permanently soon), but if you just sit there and don't move, well, basically, you have a dozen or so cesium clocks all orbiting you, and telling you what time they think it is. They also tell you what their ordits are, updated several times a day, so you can make the doppler and the time-of-flight corrections yourself.

I work part-time in Jila, where one of the world's foremost metrologists plays^H^H^H^H^Hworks (Ever heard of Bose-Einstein condensation? That lab's up two floors.) He's decided it's worth while to have a GPS receiver doing exactly this. He finds it nice to have a clock with about a part in 10^-13 absolute accuracy (for $200!) lying around. Like, to measure the frequency of some particular color of green to a few Hertz, and get it right.

Hello.
I'm gathering information to build a state-of-the-art preamp
for my ham-clubs EME-gear. There are some projects described in
the ARRL handbook, and also in the VHF-UHF manual, but -
these constructions were designed mainly in the 1970s and early 1980s.
Thers's been quite a evolution in the GaAsFET business.
Does anyone have a suggestion for a modern FET with very low NF?
And a source for the data sheet, cause I need the scatter parameters for
the device to make the rest of the circuit.

It will depend on the rig, but 5 volts strikes me as too low.

I know many radios have 12VDC open circuit voltage
on the key jack. Check the specs of your rig.

Try picking up a used AM 5 tube radio at a thrift store. It's probably
your best bet. Probably less than $5.

Hello All

I have several 7 pin PR Mallory Selp Molding Resonant Relays
RRC- SPO 1274E (175 255 marking on top)

I need to know what equipment they can be used

And their present value.

Thanks for all replys

>at the moment.
>
>

Most solid state 2 VHF and UHF amplifiers have very poor linearity. Part is due to the poor bias circuits, and part to the coupling being too light.

Too light of coupling improves efficiency on FM and CW but reduces linearity because the source impedance becomes lower than the load impedance at high drive levels.

You can do a crude test of linearity by slowing increasing drive power from zero while watching power output. Power output over power input should be the same ratio at all drive levels. If you have gain non-linearity at low power levels in the form that gain increases quickly, the PA needs more bias current. If you have gain reduction at higher drive levels the PA has either a poorly regulated bias source, or too light loading, or bad output devices.

Since the L.O.S.A is getting bigger I only post the index of
applications to the newsgroups and you can download the complete
L.O.S.A from the following places...

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

WWW:

http://www.hth.com/losa.htm

1.0 Whats is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great
ideas and many problems that are solved with the BASIC Stamp and the
main purpose of this list is to get an idea of what other people are
using their BASIC Stamps for and maybe get some inspiration or hints.

1.1 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa.htm

1.2 List of contributions

Gary,
I was a bit puzzled by the focus of the survey. Why cw vs. no-cw as
THE pressing issue to bring before WARC? Are we satisfied with the
concept of incentive licensing, as administered by VECs, with multiple
choice question pools that very young children can memorize? Is IT a
world-wide issue? As I recall, incentive licensing was supposed to
promote proficiency by dangling exclusive band segments as a carrot.
Well, technology has changed a bit in the last couple of decades. I
was "proficient" by the FCC's determination in cw, and knowledge of
am, ssb, and fm theory, but I'm certainly notproficient in digital
modes. And the insides of my current fm rigs don't resemble the old
Motorola 41v boatanchor I used to use on the .34 -.94 repeaters from
here to California. I try to keep current, but the educational
channels tell me I'm not growing any new neurons.

IF we need to make class distinctions among hams, I think interest in
modes, bands, activities, etc. should be explored as a criterion for a
way of spreading out the congestion on the air. How about 3 basic
classes of licenses (novice, tech, advanced, or whatever) with
endorsements for cw, packet, ssb, EME, ...? The commercial licensing
system uses endorsements.

I'd hope that we would forever stay away from anything that smells of
type-accepted appliance operating as a distinction from our unique

privilege of homebrewing. Also, years of experience or "service" doesn't make much sense as a criterion, and not just from the neuron-depletion effect. Just because I've driven a car for 35 years, that doesn't say anything about whether I'm a capable, courteous and responsible driver.

I am afraid that the League is focusing on the minutae, with the cw issue at the forefront. Yes, it has to be addressed, because it is an international treaty stipulation. I'd like to see more thought put into how we can continue to cope with the pressures of accelerated growth in numbers of licensees competing for bandwidth, and the attendant need for more commercializaton to "keep our numbers up". The '99 Conference will produce answers; it's supposed to. Since it is, however, a conference, I think we need to bring up some real questions.

Clues needed!! Many rigs are vastly different!! The most reliable method is a mercury whetted relay. These can be very small, but are VERY reliable!!

Thanks to the following people who provided the specs
I wanted on the various diodes:

Jim <airioch@telalink.net>
Mark <mzenier@eskimo.com>
Tom WA1RHP <tcs@cmcorp.com>
Charlie KX7L <charlier@lsid.hp.com>
Tom WB6IQD <dunnt@starbase1.caltech.edu>

Some WWW sites were also useful:
http://www.nteinc.com/
http://www.natsemi.com/
http://www.mot.com/

For the record, this is what I ended up with:

GE A327B Si, GP Rectifier, 18A, VRRM 200, VF 1.3.
Replaceable with MR1122 (12A 200V)

NAE 1N1202A 200PRV, 12A, Cathode Case.
Replaceable with NTE 5874

IR 20FQ035 Schottky Rectifier
Vrrm = 35V
If(avg) = 30A at 111 deg C
Vfm = 0.47V at Ifm (but they don't say what Ifm is)
Eas = 40 mJ
Iar = 4A (current decaying to zero in 1usec)
Irm = 150mA at Vrwm
Max Tj = 150 deg C.
If follows IR part numbering system, it's
a 20 amp diode.
Replaceable with MBR3535 (35A 35V).
Replaceable with NTE6084 (35A 45V).

M 1901-0630 Used in HP computer power supply.
This is a Motorola MR1123R,
Vrev (repetitive) = 300V
Vrev (Non-Repetitive) = 400V
If(avg) = 12.0 A
If(pk) = 75.0 A
If(peak surge) = 300A (half wave of 60 Hz sine)
Vf = 1.0V at 12A
Irev = 0.5 mA at 300V
Thermal resistance 2.5 deg C/W

M 1-1035 Used in HP computer power supply.
1901-1035 == Motorola MR881R
Vrmax = 100V
Ifpk(repetitive) = 12A
Reverse recovery time = 1uS
One cycle surge current = 200A
Max Vf at 12A = 1.4V
Leakage current at Vrmax = 0.5mA

TRW SD51 Schottky, 45PRV, 60A, Cathode Case.
Replaceable with NTE 6094 (45PRV, 60A)

Cheers,

My OLD 1965 ARRL Handbook has a transistorized one,
so surely later versions do also.
Also, Jan 1992 '73 magazine has a combined FS/Dip meter.
Its uses 1 transistor for each function.

And watch that secondary voltage rise!

While you are at it, rewind the primary and secondary because they're not designed to deliver low ESR. Better yet, move the secondary right over the primary to get rid of flux leakage, and shorten the core path to decrease flux leakage.

Then you'll have a good transformer.

I can't let this one pass. About two or three months ago I was involved in a discussion on .misc about why I supported CW. I had yet to do my tests then. My main reason for wanting to do the Morse test was the relatively easy entry into real homebrew afforded by CW TX's. Gary and others were opposed to the CW requirement in the test. I supported it for the reasons given below.

I have been quiet since then. But in the interim, I have passed my Novice and Tech exams. My CW TX is all but complete. This is not a kit, but a from-scratch homebrew project, based on a 6LR8 TV sweep tube. With the power being fed to the circuit, I will get about 35W to 40W. Gary, despite your protestations to the contrary, it is hard to beat a simple CW TX for ease of design and construction, especially when dealing with powers above a few watts. It is a great entry point. BTW, my profession involves the development of device drivers & microcontrollers and work on new CPU designs. I say this not to brag but to explain that I am no digital myope or luddite and thus am not opposed to digital modes.

This may single me out as arrogant or puritanical, but I do not consider wiring a module to a PSU as homebrew. Too much of the work has been done already. If the entry point became nothing less than some digital rig, it'd be the end of real homebrew and we'd all become module pluggers and appliance users, without any real understanding of the foundations. We would encounter few of the real, physical difficulties. One could argue that the TX could still be developed

and thence tied to the computer. But the price of the project would jump from a few tens of $'s to at least a few hundreds of $'s, with the complexity going up significantly - thus making the entry point much more expensive and more difficult.

I recognise there are many occasions when using monolithic or integrated devices is mandatory. However, I think it is a poor starting point as no gut feel for the device's operation is aquired (IMO, of course). If you do have a gut feel for the underlying science, then I maintain you'll make much better use of the integrated devices.

Again I must say that while I don't like unnecessary government interference in my life, I have a hard time opposing the requirement to learn something, especially something as easy as CW (15 minutes per night for a month folks - is that really too hard?). Some opponents of the CW requirement remind me of my childhood school colleagues who complained loudly to the teacher about having to learn something because, "I'll never use this". With the hindsight of age, one realises just how silly such sentiments are.

And again, if the CW requirement must go, then I maintain one can use the same arguments to eliminate most of the technical questions. Except for some propagation knowlege, why would anyone need to know what a transistor symbol is, or what the block diagram of a phase modulated TX is? How does that knowlege affect today's appliance operators? Would it not be a sad day if it came to that? The value in the license would be lost.

If the technical requirements of the license were dropped, how long would it be before the FCC started mandating emmision tests on homebrew equipment? It is a natural progression (regression?). Have you priced FCC emmision tests recently ($500 per half day - the usual minimum time slice)?

The CW requirement caused me to enter the field, for I am interested in its homebrew aspects. With the CW requirement, I know there are others out there with whom I'll be able to communicate using my homebrew CW TX. There is no simpler, low level, entry point than a CW TX.

Cheers,

Chris (KC5VQL)

1137. WTB: 6" Ceramic Spreaders for Open Wire Line

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-12 00:00:00 UTC
From: bk296@FreeNet.Carleton.CA
Message-ID: <519hpi$clv@freenet-news.carleton.ca>
Source record: 102517

I need enough spreaders for a 1/4 wave open wire line at 80m. 6" spacing preferred, as that will give 600 ohm surge impedance with 12 ga wire.

I have had varying opinions about how many I need, probably at least 30 for the 60+ ft feeder.

This is for a 1927 transmitter project, thanks for any help.

*** Mid Atlantic VHF Conference ***

The 20th Annual Mid-Atlantic States VHF Conference sponsored by the Mt. Airy VHF Radio Club will be held on Saturday, 5 October at the Days Inn in Horsham PA. Technical presentations relating to VHF/UHF/SHF weak signal operating will begin at 9AM.

The Days Inn is located just north of exit 27 (Willow Grove exit) of the PA Turnpike, just north of Philadelphia, in Horsham, PA. Rooms at the Days Inn can be reserved by calling 215-674-2500. Mention Pack Rats for a discount. The Days Inn is filling up quickly, so reserve soon. Additional lodging is available in the Horsham area.

*** HAMARAMA ***

On the following day, Sunday 6 Oct. the Packrats will have their annual hamfest at the Bucks County Drive In Theater, about 5 miles north of PA Tpk. exit 27 on Rte. 611. Talk-in on 146.52 simplex and the W3CCX repeater on 224.58.

Ron, WZ1V has placed the flyer for the events, including a preliminary list of presentations, on the N.E.W.S. Group web page:
http://uhavax.hartford.edu/~newsvhf/hamarama.html

For more information on the technical conference or a possible presentation slot, contact John Sortor, KB3XG, at 610-584-2489 or at JohnKB3XG@aol.com.

You're right. There were two such blocks, and they knocked out fine with a
hammer. Too bad neon sign transformers are potted; this one was
open-frame, and you can see (and get to) what's happening.

>And watch that secondary voltage rise!

That's ok, I didn't *need* 1,850 volts specifically. It's just what it
looked like with the shunts in place. 2 kV would be fine too. Or 3.

>While you are at it, rewind the primary and secondary because they're not
>designed to deliver low ESR. Better yet, move the secondary right over the
>primary to get rid of flux leakage, and shorten the core path to decrease
>flux leakage.

The primary is about 60 turns of pretty hefty (10? 12? g.) solid copper,
and the HV secondary is a bunch of ~18-20 g. solid copper. Not too bad in
the ESR department, but maybe not *the* *best*.

>Then you'll have a good transformer.

Hey! I didn't pay a cent for this thing! It may not be a Peter Dahl
Hypersil® Megabuck thing, but it was free! If it manages to run a HeNe or
a PMT (which it will) it's already pure bonus. But probably a few more
watts can be coaxed out of it than that.

Not bad for a banged-up microwave by the side of the road, and half an
hour with a screwdriver.

Sorry, you must be lieing. According to Carl-The-Omniscent, the CW examination scares away the technical elite. The fact that you enjoy CW means that you absolutely, positively CANNOT be an engineer. If you were, you wouldn't like CW, and you'd think amateur radio consists of a "bunch of geeks who know less about RF than you've forgotten".

>> commercial products out there?

This is an evolving subject. I just bought DSP Blaster from K6STI (k6sti@N2.net) which does some filtering, noise reduction, graphics displays on the SoundBlaster cards only. Haven't tried it as I'm waiting on a new Pentium Pro and he has traditionally used a copy protect mechanism of writing a hidden file on the disk that makes it a bit hard to change from machine to machine. The manual looks good and he always seems to do good work so I'm optimistic. The down side is that, from looking on the WEB at some user contributed SoundBlaster info, Creative really does not make much data available on how to do anything original with their card.

The alternative it to pick up one of the cards based on the Analog Devices 2115 DSP chip. Cardinal, Wearnes, Orchid, etc had cards based on that series, but they seem to have disappeared from the computer market. I picked up one at Dayton for $25 in an OEM pack this year. AD had a very good evaluation board with lots of software for about $100, but suspect those are gone. You can do real DSP with those and it is unfortunate that the temporary phenomonen of the combination of consumer related (cheap) cards with cheap development software was not adopted quicker by the ham community.

Comer Communications has a complete DSP transceiver on the market and has been at Dayton the past two years. It uses a Wearnes soundcard and another PC card for the whole thing. It seemed to be priced at a level which was high in comparison to the low ham lines and did not really have great RX IP, NF, etc., but is worth a look. Try a WEB browser. I had thought of trying to buy just the DSP part.

Of course the moon bounce guys have several versions of signal processing, again available on the WEB.

It's doable, but challenging to get things together.

NOW YOU CAN HAVE THEM TOO!

Discrete TTL/CMOS technology is old fashioned and cost you lots in terms of space and power.

The software and equipment needed to program your own PAL/GAL chips can cost in the thousands.

PAL/GAL technology can reduce chip count up to 90% and in many cases are faster than TTL/CMOS technology.

This saves you time, money and board space.

If you can describe it and it can be programmed, We can program it.

Custom logic chips are a lot cheaper than you think.

No order is too big or too small.

We specialize in providing quality fast turnaround to individuals, students, hobbiests, companys -- whatever the situation.

E-MAIL US TODAY with your logic description and we will send you a quote.

>work so I'm optimistic. The down side is that, from looking on the WEB at
>some user contributed SoundBlaster info, Creative really does not make much
>data available on how to do anything original with their card.

[snip]

One thing to bear in mind is that if you're going to write for Windows,
it really doesn't matter *what* sound card you're using, if you do the
DSP routines in software, and just use the card for samples in -> samples
out. On a faster processor, there's no reason *not* to do it that way.

Not that I claim it's the best example, but my Win32 SSTV program
runs only 6 to 9% CPU utilization on a P90 when "sniffing" for an
SSTV signal in the noise. That's DSP and stat recog both running,
as well as a small spectral histogram window.

Of course, the quality and efficiency of the device driver make a
difference. The latest Win95 driver from Creative will give you
full duplex, and is very efficient and well-written. (For their
cards, of course..)

Anyone that's interested in creating some really unique 'amateur' apps
for Win32 could do worse than to investigate the low-level audio API.
It's not for the neophyte, but with a little sticktoitivness, you can
get it figured out.

I'm sorry, I thought it was for a SSB or CW PA. For your application it's a good deal.

What I was trying to say is voltage sag under load will be much more likely to limit the power than heating even if the magnetic shunts are knocked out, since the flux path, coupling, and wire guage are all selected for a different application.

Voltage stability with load changes are only a factor on CW or SSB, where the voltage sag causes envelope distortion. So please excuse my snide social commentary.

Well If you still want JAN's number it's 1-800-JAN-XTAL.

No, this is not a sig.

1156. Re: How do I change a normal radio (lw,mw,fm,) into a shortwave one?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-13 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseDxotwE.6xB@netcom.com>
Source record: 102393

One fairly quick and reasonable way to do this is to build a "downconverter"
to convert the shortwave band of interest, say 5.7 to 6.4 MHz to 0.7 to 1.4MHz,
and feeding that to the AM radio's front end. You'd need a 5MHz local osc
and a mixer stage, and also a filter to remove AM radio stations on the
0.5 to 1.7MHz band from leaking thru. Also a filter to remove hetrodyne
images from around 3.6 to 4.5 MHz.

Otherwise, you'd probably be better off buying a shortwave set, than changing
the LC circuits in your AM radio's front end.

You might as well forget obtaining ceramic spacers but if you do, congratulations! A modern approach is to obtain some of the high pressure air hose material used in garages and machine shops. This material usually yellow and coiled in loops. Cut this material in six + inch lengths, drill a hole suitable for #12 wire and cut two slits from the end of the "spreader" into the drilled hole. Works better, lasts longer and is cheaper especially along the saltwater coasts! Cliff Buttschardt K7RR

1160. Is JAN Crystal poor quality? / phone number

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-13 00:00:00 UTC
From: and@pacifier.com
Message-ID: <and-1309961922480001@ip133.pdx1.pacifier.com>
Source record: 102397

In a previous posting, someone claimed that JAN Crystals were of poor quality- and that one was better off buying from International Crystal.

Can anyone else confirm this? I was about to buy $150 or so of crystals from them for my Drake R4-C for shortwave and WARC bands.

Also, does International Crystal ship COD? JAN does not any more.

Lastly, the area code at JAN has changed to 941.

Thanks.

Hi,
You can get power resistors with thermal fuses built in. Basically if
you exceed the power rating a sprung loaded soldered joint opens the
circuit. The gap is large enough not to arc with 5KV. They are available
from most good component suppliers.

Regards, Nick, G6AWT (UK).

Gee, 41V? That must have been some vibrator. I had a 40D myself.

Ted, the reason the Morse testing issue is central is that it is
the only requirement spelled out in the international regulations,
IE "send correctly by hand and receive by ear texts in the International
Code". There is no required form for other testing. The regulations
simply say that each national administration shall determine if the
applicant is competent to operate an amateur radio station. The means
of such determination is left up to individual administrations. Thus
there is nothing else to address at the WRC about testing other than
the Morse issue.

Other testing issues, license class distinctions, if any,
bandplans, etc are matters for each national administration
to address. We needn't concern ourselves with these issues
at the WRC.

There are other relevant issues which will be discussed at
the WRC, however. Notably the strong third party traffic
prohibition will be on the table as well as the language
limiting the content of amateur transmissions to "in plain
language and shall be limited to messages of a technical
nature relating to tests and to remarks of a personal
character for which, by reason of their unimportance,
recourse to the public telecommunications service is
not justified."

Those limits are generally considerably stronger than we enforce domestically. The plain language restriction has become vexing because it appears to eliminate the possibility of digital signatures to verify identity. There is no mention whatsoever of amateurs' public service and emergency roles in the international regulations. Amateur radio is defined only as a service for private technical investigation and self-training in the radio arts. It would be useful if we could get language inserted recognizing our role in public service and emergency communications. That would make the service's justification of spectral claims stronger. To do so, however, the third party prohibition must be stricken, and the content rule liberalized.

>IF we need to make class distinctions among hams, I think interest in
>modes, bands, activities, etc. should be explored as a criterion for a
>way of spreading out the congestion on the air. How about 3 basic
>classes of licenses (novice, tech, advanced, or whatever) with
>endorsements for cw, packet, ssb, EME, ...? The commercial licensing
>system uses endorsements.

The problem with that system is how do you deal with new modes? Remember we are a service for technical investigation and self training. If we can't experiment with a new mode until we are tested on it, who will write the test? If the new mode is just a gleam in the experimenter's eye, how can a test already be prepared? We need to retain the maximum possible flexibility here since it cuts to the very heart of what amateur radio is supposed to be about.

>I'd hope that we would forever stay away from anything that smells of
>type-accepted appliance operating as a distinction from our unique
>privilege of homebrewing. Also, years of experience or "service"
>doesn't make much sense as a criterion, and not just from the
>neuron-depletion effect. Just because I've driven a car for 35 years,
>that doesn't say anything about whether I'm a capable, courteous and
>responsible driver.

The one thing that makes amateur radio a unique service is the permission (encouragement actually) for us to experiment, build, modify, and repair radio equipment. That is central to the purpose of amateur radio. It must not be lost, because if it is, we're no different from CB or any other personal radio service. Our self-training charter means we are to use amateur radio as a vehicle for lifelong learning. So time in grade *should* equate to more knowledge. We currently don't do anything to encourage that, and I'm not sure if we can. You know the old adage, "You can lead a horse to water, but you can't make him drink." We can offer the opportunity for lifelong learning, but there's no practical way to require it.

There is no test for courtesy or responsibility. That is something you have to demonstrate every day. We have only peer pressure, and the increasingly less likely threat of enforcement action, to maintain

order. The one thing we do have is an insistence on amateurs using their true names (their call signs) on the air. This is essential. If, as on CB, they can hide behind a handle, people behave as if they were masked and robed Klansmen, free to play out any antisocial fantasy they like with little fear that it will have reprecussions on their ordinary lives. This is the thing which forces amateurs to self-police, IE police themselves, in their behavior on the air. The certain knowledge that other people know who they really are makes them behave more respectably than if they could consider themselves part of an anonymous masked mob.

This is the one good thing about the compulsion amateurs have for collecting postal cards, and the anal need to keep logs. It serves to reinforce the need to have correct identification for every station worked. While it was a pain, the relaxing of the requirement to keep a log was probably a mistake, and the removal of the requirement to give both the call sign of the station with which you are talking as well as your own during IDs is also probably a mistake. If you want to point to one thing that has caused a deterioration in decorum on the amateur bands, this would be it.

>I am afraid that the League is focusing on the minutae, with the cw
>issue at the forefront. Yes, it has to be addressed, because it is an
>international treaty stipulation. I'd like to see more thought put
>into how we can continue to cope with the pressures of accelerated

>attendant need for more commercializaton to "keep our numbers up".
>The '99 Conference will produce answers; it's supposed to. Since it
>is, however, a conference, I think we need to bring up some real
>questions.

As I mentioned, WRC99 is not the proper forum for those sorts of things. Those are issues we have to address on a national level, and more appropriately, internally within the service when possible. We do need to maintain a solid growth rate, not only to provide the political muscle we need to keep our allocations, but also to keep the service's demographics healthy. We cannot afford to allow the service to stagnate and grow increasingly grey as it did in the period between the imposition of Incentive (to pass faster code tests) Licensing and the creation of the code test free Tech.

We have experienced a 33% increase in the number of amateurs in the last 5 years. That has made some amateurs uncomfortable. I have very little sympathy for them. If they had not been so pig headed about Morse testing all those years from 1968 to 1991, amateur growth could have been a nice steady 6% a year over two decades, we'd be about 1 million strong today, and the service would have much healthier demographics than it has had. The code test free Tech has begun to turn things around. The average age of amateurs has declined by 6 years over the last 5 years, but

it is still too high at 52. It should be about 42. Amateur radio
still needs another dose of strong medicine to unclog the pipes
and put things right.

1171. Crystal sets again... and the usual nostalgia &c

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-14 00:00:00 UTC
From: nyoung@nova.wright.edu
Message-ID: <1996Sep14.091558@nova.wright.edu>
Source record: 102401

Ah, crystal sets! I just finished fixing one up for my youngest. It's a modified version of the Modern Radio Labs #2 DX crystal set. Instead of a tapped coil, I gave the set a "slider." So far it has managed SW -- picked up some kind of Japanese program last night... And BBC is a piece of cake -- and a lot of local stations. Nice set up.

I've also started building another set for myself, using a modified version of the MRL #2 and a "Navy Loose Coupler" set up for selectivity/antenna matching. That one's gonna be a monster, 'cause the largest of the two coils is about 3 inches in diameter. One option that I'm leaving for myself is (a) switchable detector options and (b) rheostat control of bias voltage for a carborundum detector.

The beauty of crystal sets -- at least to me -- is their inherent simplicity and the pleasure of making a radio that works for free. They teach some interesting theory of L/C circuitry and coupling-vs-selectivity/sensitivity, and they allow the builder/user/youngster/curmudgeon-turned-nostalgic to relive a small chunk of the history of socio-scientific magic.

I also might add that Peter Jensen's (VK2AQJ/G4GZT) book _In Marconi's Footsteps: 1894-1920: Early Radio_ is a wonderfully well-written tour of the times and places of the beginnings of the entire electronics/communication revolution of which this computer connectivity is only a small but continuing part. Jensen shows pictures, schematics, drawings, details and construction hints of everything that means _real_ radio. Tube sets he covers briefly. Crystal sets, coherers, quenched and rotary sparks, antenna couplers, interrupters, and magnetic detectors he covers in detail. I liked the book so much -- borrowed a friend's copy first -- that I sprung the $39 for a special order through the local book store.

And there's always MRL Handbook #3, _Crystal Detectors_ with 32 different minerals -- beyond PbS Galena -- that make for interesting experiments with cats' whiskers and patient probing of rocky surfaces. Too bad ol' Elmer ain't around to see how much craziness radio loonies can get into... even this far past the first arcs and sparks of some 85 years ago.

>
>I was a bit puzzled by the focus of the survey. Why cw vs. no-cw as
>THE pressing issue to bring before WARC?

Because the lack of growth, particularly in terms of the number of technically-inclined folks who are turned off/away by the CW requirement is the biggest threat to the future of ham radio.

>Are we satisfied with the
>concept of incentive licensing, as administered by VECs, with multiple
>choice question pools that very young children can memorize? Is IT a
>world-wide issue? As I recall, incentive licensing was supposed to
>promote proficiency by dangling exclusive band segments as a carrot.

No, I'm not ... and I don't think many are ... all the current scheme "promotes" (forces) is an increasing proficiency in CW "skills."

>Well, technology has changed a bit in the last couple of decades.

Technology per se HAS changed ... unfortunately, for the most part, ham radio technology HAS NOT. We're still using (and insisting on, and being driven by outdated regulations to use) outdated technologies.

>
>IF we need to make class distinctions among hams, I think interest in
>modes, bands, activities, etc. should be explored as a criterion for a
>way of spreading out the congestion on the air.

"Spreading out the congestion on the air" is NOT a legitimate reason for balkanizing the ham community ... if there's congestion, we need to exploit modern, technical solutions to increase our efficiency of spectral use to eliminate/control it ... not politically hamstring our ability to improve, explore, and experiment with new techniques.

>How about 3 basic
>classes of licenses (novice, tech, advanced, or whatever) with
>endorsements for cw, packet, ssb, EME, ...? The commercial licensing
>system uses endorsements.
>

More balkanizing ... I agree with Gary's recent post AGAINST anything but ONE license class. If people want some sort of proficiency endorsement certificate (another form of "wallpaper") that would be something that the ARRL could provide ... just like DXCC and the myriad

of other ego-gratification certificates that they currently offer.

>I'd hope that we would forever stay away from anything that smells of
>type-accepted appliance operating as a distinction from our unique
>privilege of homebrewing.

Agreed ... this will simply raise the cost of commercially-produced equipment DRAMATICALLY and limit the experimenter's freedom to experiment. We have far too many regulations that encompass the latter already.

>Also, years of experience or "service"
>doesn't make much sense as a criterion, and not just from the
>neuron-depletion effect. Just because I've driven a car for 35 years,
>that doesn't say anything about whether I'm a capable, courteous and
>responsible driver.
>

Neither does a mandatory CW test serve as a "lid filter" ... that's painfully obvious by listening to the bands ...

>I am afraid that the League is focusing on the minutae, with the cw
>issue at the forefront. Yes, it has to be addressed, because it is an
>international treaty stipulation.

I agree with the second statement, but not the first ... the CW issue is NOT "minutae" (sic) ... it is THE most important issue we need to address for the future of ham radio.

>I'd like to see more thought put
>into how we can continue to cope with the pressures of accelerated
>growth in numbers of licensees competing for bandwidth, and the
>attendant need for more commercializaton to "keep our numbers up".

This a technical issue which demands technical solutions, NOT political ones ...

>The '99 Conference will produce answers; it's supposed to. Since it

I agree to an extent ... if it's all you say, it's simply "final assembly" and doesn't merit as much "credit" as "design-from-scratch" projects. We definitely need more of the latter, though there IS a lot of that going on ...

> If
>the entry point became nothing less than some digital rig, it'd be the end of
>real homebrew and we'd all become module pluggers and appliance users, without
>any real understanding of the foundations.

I don't understand why you assert this ... it's quite possible to start from scratch and design new and wonderful things quite digital ... you take a uP, some RAM/EPROM, some gates, PALs, etc. and build it up (wire-wrap or PCB) ... then you interface it to your PC and voila!

>We would encounter few of the real,
>physical difficulties. One could argue that the TX could still be developed
>and thence tied to the computer. But the price of the project would jump from
>a few tens of $'s to at least a few hundreds of $'s, with the complexity going

>difficult.

Again, I find your argument unconvincing ... uPs are cheap ... I just eliminated over $30 in parts cost on a design I'm responsible for at work by ADDING two *two dollar* microcontrollers to replace some things that were originally designed in a rather backward fashion. (I "inherited" the poor design from a predecessor and was tasked with 1st making it work (which it didn't, now it does), then cost-reducing it (which I'm doing)).

>
>I recognise there are many occasions when using monolithic or integrated

Try building a UHF radio with some of the highly-integrated GaAs or silicon MIMIC "building blocks" that are available today, then tell me that ... if you don't have a "gut feel" for the underlying science, you'll develop/learn it fast, or you'll never get them to work.

Garrie,

Thanks for making that point again ... it's something the pro-CW folks choose to ignore.

I have NEVER, EVER, in over ten years of debating this issue, seen a no-code advocate actually advocate the *banning* of CW from the bands. Not once. (of course, now that I've said that, one of the pro-coders will probably start up a phony "ban the code" thread in an effort to taint the discussion with a bunch of bogus anti-no-code distortions).

BUT - those sections of the band reserved for non-phone uses shrink as
more and more phone operators crowd the remainder. In the '50's, 75
meters was only 200 kHz, and there was no phone on 40 at all!

I suspect that in 20-30 years, there will be no parts of the band
reserved for non-phone usage. It will all then be by "gentlemens
agreement".

Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.policy,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I hear packet stations pushing JUNO, read this:

At JUNO the customer philosophy appears to be "the customer comes last."
I had an account with them (kotzebue@juno.com) and as you will read
below I supported them strongly. However they have a rule if anyone at
all complains about you they will terminate your service. It does not
matter whether the complaint was justified or not or even if it had
anything whatever to do with your JUNO account, you will be terminated.
What is even worse I was terminated without ANY notice and they
were unresponsive to any EMAIL (except their automated replies). Also if
I tried their tech support and I was on hold for a long time and when
you do get through they did not followup (so I do not really know why my
account was cancelled or even if it is a technical problem, I am
surmising I was removed). Thus if you had set to receive all your Email
via that account, you are screwed as those that write you will have
their mail bounce back.

Even when JUNO works it take me several calls to avoid crashes, hangups etc.

Now I do have another JUNO account as their software was simple to
overcome and simply sign up another account. I was inconvienanced by the
termination but only a bit as I had two other Email accounts.

Here is what I told them when they said they had a complaint about them.
(I got NO response).

FIRST I am one of your biggest supporters. I have sent out messages to
over 50 friends who were interested in your service. The more users the more
revenue you gain from advertisers.

I send no internet users unsolicited messages from my Juno account.
I post to the internet via my Internet Service Provider, which is not
you.

If I have my address listed in a signature how does that violate any
terms of an agreement? You are well aware almost anyone will complain about
almost anything on the internet.

I only send messages to those that send me messages except in a few rare cases.
I will be mindful of your concerns but please do not defend those that would
make false and/or misleading claims.

As far as violating the terms of the agreement, I read the terms and the
only thing that comes close follows:

3.4. . You agree that you will not interfere with any other person's use and enjoyment of the Service or any other online service.

That sentence is impossible to comply with as written. If I post a message saying I do not like Nazis (which I did) that can be inferred as "intefering with someone's enjoyment of any other online service." Thus do expect all your users to have no opinions on anything? If you wish to deny me service based on that provision I will go from being your greatest advocate to a very unhappy former customer and just as I have not kept my pleasure of using Juno to myself, I will not keep my displeaure to myself either.

Burt Fisher

Here is the complaint they sent me which caused me to respond above:

On Tue, 06 Aug 1996 13:07:53 -0400 Juno Postmaster <postmaster@juno.com> writes:

The largest deficiency in the Hobby today lies in the mindset of those who enter thinking Amateur Radio is a kind of "Advanced CB" world, and who bring with them the same whining and culturally bankrupt attitudes that prevail on 27 mhz. This thinking is furthered by the present perception that numbers alone will save us from being made fodder by the ever increasing demands of a profit driven Communications Industry.

Morse, while certainly an ancient form of communication, is essentially like any other language. It is easy to learn and can be picked up by children in a short time, why not the rest of the population? It strikes me that those who spend so much time complaining about the code would more efficiently use the oxygen and resources they consume on this earth by learning and teaching the code, therby ensuring it's future use in our hobby.

A Filter??? Maybe not, but detractors should spend some time on 30 meters listening to the new Hams and how hard they work at becoming proficient CW operators...it's heartening to hear.

Perhaps it would be better for all of us to heal the wounds that divide us and present a united front at Warc. Our enemies are many and their percieved spectrum needs large. I believe our entire hobby is at stake.

I want to build a discone for my frg9600. I thought i'd make
it out of .2" dia aluminum rod that's in the junk box.

The disk and the cone designs are easily determined from
engineering handbooks. But they don't say much about what goes on
at the apex of the cone. Sounds like the cone should go to a point
if possible. But you have to stick a support pipe up the middle.

Anyone got ideas on how to configure the mechanical parts and
electrical connection where
the cone joins the disk? I'd like it to be strong enough to withstand
at least the first windstorm.

Oh, cheap materials is better...
thanks, miker

1189. Strange balanced modulator design question

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-15 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDxr5uH.38D@netcom.com>
Source record: 102419

I am looking at schematic of a Japanese SSB transceiver. It has a type of balanced modulator I've never seen before. The audio from the mic is amplified once by a conventional class A transistor amp, then fed into an IC. The IC has a 5 MHz crystal. Based on the block diagram, the purpose of the IC is to take 300-2700 Hz audio and shift it to 4400-2000 Hz, before it is fed into a balanced modulator using four diodes.

Does anyone have an idea why they would shift and invert the audio passband before sending it to the balanced modulator? There are easier ways of getting the opposite sideband (move the BFO crystal relative to the filter) and I can't imagine why they'd want to shift the audio up, except maybe to improve opposite sideband supression (it's a very simple 4 pole crystal ladder filter). Could the sideband inversion just be an artifact of the intended frequency shift? One clue is they move the BFO (by changing load on the bfo crystal) about 3800 Hz when going between TX and RX modes. The audio processor chip I'm referring to is only in the TX audio path - the RX audio path is completely conventional (it's a transceiver).

The chip doing the magic is a M64021, and I have no other specs on it.

Any comments?

Subaru sailed into port late Saturday afternoon, at San Francisco CA. He had
suffered generator power failures that cut off his radio communications.

Farm supply stores....3 foot lengths of fiberglass rod.. 3/8" dia.
Used for spreaders for electric fence. There are bags of clips
avaliable to hold the wire...or drill holes etc. At least they
are the right color..... K2RK

==========

If you want to be authentic, make a 1927 antenna for that 1927 transmitter: Make the spacers from a hardwood like oak, and boil the wood pieces in paraffin to waterproof them.

I am trusting my memory from reading '30's ARRL handbooks in the '50's on this, but I believe most "ladder-line" spacers in 1927 were wood.

Probably hardwood dowels from the hardware store, and paraffin block from the grocery store (still used in home "canning") would do the job for you.

This is just a guess, but they may be using an asymmetrical SSB
filter, in which case you can't simply shift the BFO, you have to
flip the sidebands elsewhere.

That depends on the rig. There are no standards; not even polarity.
I've had tube rigs that had nearly a hundred volts across the key
contacts. An HT may have only one or two volts at a couple mA.

Source record: 102429

Got alot of mail regarding question about JAN crystal quality.

Evidently, lots of people have had excellent results with JAN.

I imagine problems with drift were the result of lousy circuit design and not the crystal.

Maybe they were using a 1n4007 diode in the osc for the ubiquitous ARRL patented gate diode clamp. :) :)

1200. Hamtronics VHF/UHF transverters any good?

Anybody out there build (or buy) and use the Hamtronics VHF and UHF transmit and receive transverters? Do they work well? They seem quite reasonably priced. Any comparison to other company's transverters? I'm active on 6M and during the VHF/UHF contests I always get asked to try 2M/222/432. No gear (SSB) for these bands. Myself and KB9IQR plan to work the June VHF QSO Party from EN67 each year and I'm sure people would like to get this rare grid on bands other than 6M. All info greatly appreciated.

HELLO!!! WAKE UP!!! YOU OVERSLEPT!!! THIS IS NOT THE '50S!!!!!!!!!!!!

Times have changed ... that happens ... it's part of life.
Times will continue to change ... if you're not prepared to deal with
that, you're in for continuing dissappointment.

>I suspect that in 20-30 years, there will be no parts of the band
>reserved for non-phone usage. It will all then be by "gentlemens
>agreement".

Realistically, in 20-30 years, there will not BE any ham bands if we
don't modernize and grow ... the spectrum is too valuable for other uses
to devote so much of it to 150 year old nostalgia "technology."

Hams USED to be the INVENTORS, the VISIONARIES in the radio
communications field ... always ready to invent or adopt new things to
communicate better ... NOT ANY MORE ... today's hams are stagnated in
the technology of the 1950s (or earlier) and bitch and moan and whine
any time someone proposes the use of something new and better.

If you're not prepared to be a part of the solution, please at least try
not to be a part of the problem ... get out of the way ... stop being
such obstructionists ... let the visionaries, the younger people (in age
or spirit, or both, and the newcomers lead the way to the future.

If I'm going to "learn" any other languages, it's going to be something a heck of a lot more useful; something like Japanese or Spanish.

> It strikes me that those who spend so much time
> complaining about the code would more efficiently use the oxygen and
> resources they consume on this earth by learning and teaching the
> code, therby ensuring it's future use in our hobby.

One question: Why should we ensure its continued use? It's slow, and not terribly efficient as far as wpm per kHz go. (20 wpm is less than 2 char/sec; 10 bits/sec if you encode it in a 5 bit system like Baudot. That should need at most 10 Hz of bandwith. CW needs a few hundred Hz. I can get ten times that throughput, error free, using 300 baud packet on HF, with not much more bandwidth.)

I don't know of anyone complaining about the USE of CW on the bands; they are complaining about the REQUIREMENT of having to become proficient at a higher-than-minimum speed in a mode they have absolutely no desire to operate.

I have a degree in Electrical Engineering, specializing in digital communications and computer science. While my ham ticket was useful in pursuing my degree, I had no need for knowing Morse (except for getting my Tech ticket 10 years ago). Even now, the only use that I have for getting a higher class license is to shut up those people whose only argument is that I'm simply trying to get out of learning the code.

> A Filter??? Maybe not,

Maybe??? Take a listen on 20m. EVERY (legal) user of that band with a US callsign passed a minimum of a 13 wpm code test. It's worse than the CB bands.

I think that the price of the radios makes a better filter than any kind of CW exam.

> but detractors should spend some time on 30
> meters listening to the new Hams and how hard they work at becoming

> proficient CW operators...it's heartening to hear.

More power to them. Nobody is proposing that CW operation be banned, or
even discouraged.

>perception that numbers alone will save us from being made fodder by
>the ever increasing demands of a profit driven Communications Industry.
>

Not numbers alone ... but technical progress ... more efficient use of
our spectrum by larger numbers of hams, performing more useful public
service work and doing more experimentation and development of new
technologies ... those are the things that will save ham radio ...

>Morse, while certainly an ancient form of communication, is essentially
>like any other language. It is easy to learn and can be picked up by
>children in a short time, why not the rest of the population?

With this argument, you could just as well substitute "Nursery Rhymes"
for "Morse" and it would fit just fine. Would that make a test in
Nursery Rhymes a reasonable testing requirement to obtain a license
permitting access to HF spectrum???

>It
>strikes me that those who spend so much time complaining about the code
>would more efficiently use the oxygen and resources they consume on this
>earth by learning and teaching the code, therby ensuring it's future use
>in our hobby.
>

We couldn't care less if "Morse's future is ensured" ... nobody else in
the world does either, except for a few thousands of backward hams,
clinging to antiquated technologies like some sort for religious icons.

>A Filter??? Maybe not, but detractors should spend some time on 30
>meters listening to the new Hams and how hard they work at becoming
>proficient CW operators...it's heartening to hear.
>

If someone WANTS to learn Morse, fine ... otherwise, there's not one
iota of useful purpose in forcing them to learn it ... and there's
significant harm in banishing them for not learning it ...

>Perhaps it would be better for all of us to heal the wounds that divide
>us and present a united front at Warc. Our enemies are many and their
>percieved spectrum needs large. I believe our entire hobby is at stake.

1205. can Drake one-up Japanese $5000 computers (radios?)

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-15 00:00:00 UTC
From: and@pacifier.com
Message-ID: <19960915194915.aaaa000lu@babyblue.cs.yale.edu>
Source record: 102435

Was going to put in order to JAN Crystals for about $150 of range crystals for R4-C: two for each WARC band, and one each for the major SW broadcasting bands.

However, I heard that you guys still sell these. Is this true? I though I had heard before that you no longer did this.

Also, do you know anything about proposal from Network Sciences to start manufacturing filters for Drake (and Collins) again? They put out a survey to see if there was interest and I responded in affirmative.
--------------more importantly:

Here have homebuilt rcvr I call R4-DMOS. Uses same premix scheme as R4-C, but has Makhinson Front End and DMOS commutating mixer. Provides 112 db dynamic range with preamp *on*. Has synchronous sample-and-hold AM demod that doubles as product detector for cw and ssb.

Also uses variable varactor tuned IF amp/IF filter in distributed topology, which replaces $100's of filters.

A hybrid DDS/PLL ultra low noise synth is in the making for the rcvr. Just need to make uP controller for the hardware.

If I can build such a rcvr for a few hundred dollars, why can't you guys????

You could capitalize on the fact that most
rf designers would be embarrassed to be on the design team of one of those $5000 Japanese rigs that has poorer performance than some of the circuits in the 1970's "Solid State Design for the Radio Amateur" book.

If Drake would make such a xcvr/rcvr I would buy it. It wouldn't be a question of which disributor has the better price, etc etc Or who can spend the most advertising dollars- it would be clear techological superiority,. and everyone except the most green CBers turned no-coders would tell the difference.

I hope you pass this email to your higher-ups.

Thanks, Rob.

1206. RF Tight Enclosures FS

Last Fleamarket I found a fellow selling a box of Hammond 5900 cast aluminum rf tight enclosures, model #160. I recognized them for what they were, and was certain that someone would find them very useful for homebrewing gear.
They are approximately 4.5 x 7.125 x 2 inches. All of the units are used, and have about 6 1/16 dia holes drilled in the bottom. Most have an alternator noise suppressor circuit built into the enclosure (they are free, you're paying for the box).

I was able to buy these as a lot for $10 each. If you have a need for an RF tight enclosure for VHF/UHF circuits, this is the time to get a few and stock-pile them. My price is the same as I paid, plus whatever it takes to mail them to you. Since I only rarely check into the homebrew page, please contact me directly via e-mail.

>
If this is what it seems, it's pretty clever. Seems that the 300-2700 hz
audio is mixed with a 4700HZ signal to get a difference product of
4400-2000 HZ...the original audio passband has been shifted up 4700 Hz
and frequency inverted. The crystal filter used for sideband suppression
now can be very simple, since its job is much easier. The upper and
lower sidebands are now 4000 Hz apart at their closest points, instead
of 600 Hz. A simple and relatively sloppy filter can easily filter out
the unwanted sideband. The audio inversion is easily fixed by shifting
the operating frequency to the opposite side of carrier relative to
where it originally was...hence the 3800 Hz carrier shift on transmit.

To all,

We are looking for a simple rugged, TURNKEY, resellable, FCC approved device for transmitting serial data to a palm top PC from our weatherstation.

Range: 1 mile max

Problems: EMI, other nearby communication devices, this is a little outside our field (custom weatherstations), 12v power supply

What's available? Who can we talk to?

Thanks in advance for any information.

Tenley Shewmake omb00642@mail.wvnet.edu

Hello all

I have decided to find a home for this 6' monster or I will part him out within month. It is presently under canvas on my back deck and I wont have anywhere to store it for the winter. Have to have $400. and you be close by to PU and carry away.

All is there, Bauer FJ-1000B uses pr 4-400s for modulators and pr 4-400 PAs. Everything is common parts and available to restore for 160m. Presently crystaled on 1490kc, but will drive with Heath or Johnson vfo. Osc 6AG7, buff 807 pushing 4-400 in par. Speech transf input to 807s driving 4-400 in pp.

Problem: Yep, one main problem; the HV trans has shorted primary. However the modulation trans is new as well as power supply oil filter caps.

One saving grace in weight. The cabinet is aluminum with steel in bottom where transf and heavy stuff go. All trnas and heavy stuff is out (all wires marked to put back) so is easy to carry in van or large pu.

Contact Dee Almquist of SOUND IN MIND http://home.rica.net/soundnmind or soundnmind@rica.net or Ph:540-249-3161 fax:540-249-5064 voice mail 800-755-2365

I'm near Waynesboro, Va. off I-64 & I-81

Hi Garrie,
The reason I mentioned homebrewing is that Carl claimed CW ops
know nothing of how their radios work. He's convinced himself that
those who favor CW are appliance operators. Then he uses this
false belief as a basis for the purging of the CW tests, thinking
that CW is somehow holding us back technologically. He never considers
the fact that many of us have found our niche and are happy using the
present modes available to us.

Of course, if the tests are eliminated, watch his company's sales of HF
equipment soar!

Jeff KH2PZ (using homebrew CW gear - I *do* know how my radios work!)

I saw something come across my desk about a month ago. Allen Bradley will
no longer be manufacturing carbon composition resistors. As far as I
know, they are the last manufacturer to make CC resistors, at least in the
1/4 to 10 Watt power range. There may still be someone making the big
'uns somewhere.

Hi folks,

The above says it all. JRC claim they didn't make it although I have a tube and a socket from different sources and they are both clearly labelled JRC.

It looks like a 500W plate dissipation tetrode. all the connections are concentric so it may go to a respectable frequency. The socket doesn't look as though it is suited for VHF or above though.

All assistance greatly appreciated.

Best regards to all

I'm just speculating as to what that modulator circuit might be like...

If complexity and expense were no object, why not run the audio through an audio band pass filter and then through an A/D sampler (aka mixer) to put the signal at 4000 to 7100 Hz, or something like that. Then, using more filtering (switched capacitor?) and the phasing method of SSB, one could make a nice, low distortion signal. Could this be what those clever Japanese were doing?

Once again. Please let's move the no-code/code debate back to ham.policy!!! This is all interesting but the *WRONG* place.

BTW Chris asked:

If the technical requirements of the license were dropped, how long would it be before the FCC started mandating emmision tests on homebrew equipment?

The answer to this question is 19 (?) years ago!! Read part 97 and you will see that about that time frame part 97 got added constraints on spurious emmisions. It's funny that there were no quantitative requirements on harmonics/etc prior to that time. I do recall in the early 70's reading about folks getting nasty-grams from the FCC for not suppressing harmonics adequately.

I suspect it's some of this... The radio is a 144 MHz SSB HT, and based
on my friend's evaluation in Japan, he reported that the transmitted audio
quality was considered unusually good (describing it as a "human voice",
as opposed to a "robot voice" which afflicts most SSB transmissions). I
suspect the primary goal was to improve opposite sideband supression, however,
it also might have the effect of reducing group delay distortion through
the SSB filter (a simple 4-pole job). In any event, the interesting thing
is that the audio processing is done with a single chip and just a few external
components.

>
>Anybody out there build (or buy) and use the Hamtronics VHF and UHF
>transmit and receive transverters? Do they work well? They seem quite
>reasonably priced.

Hi,

A couple of years ago I purchased the 220 MHz, as well as the 440 Mhz exciter kits from Hamtronics (can't remember model #s). They were relatively easy to assemble, but I think somewhat overpriced. The 440 version worked fairly well, however, I would definitely recommend the TXCO or crystal oven option, since it is nor exceptionally stable through even small temperature changes. The Tx audio quality is acceptable, but not great. Nice compact design :)

The 220 MHz version is another story though. Although similar in design to the aforementioned model, it has been nothing but trouble. It was crystalled to work on 224.30, which it does, however, it has a spur of almost equal magnitude on 448.60. Thinking it may have been a simple, common, or at least previously reported problem, I called Hamtronics' tech support line for assistance. The tech with whom I spoke, was rather disinterested and basically stated that, since it was a kit, I had obviously constructed it wrong and it wasn't their problem. I then asked assistance from a friend who is an experienced Motorola technician, and he was equally stumped. He received basically the same response from Hamtronics. At this point: <$100 kit is useless.

The bottom line is: if you buy it assembled, it probably will work fine. If you assemble it maybe - maybe not, but don't expect helpful, friendly support, you're on your own. IMHO: Proceed with caution or go elsewhere.

Sorry about the long reply ;)

>-Scott- N0EDV
About two years ago I bought the Hamtronics rec and trans converter
kits for 2 meters. They went together very easy and worked the first
time I fired them up. No spurs and all within spec. I found the cost
of the kits to be very reasonable. The transverter is mainly used as
an I.F. for 10ghz but they worked just fine as intended.
Just my own experience....

Get about 3 meters(9 ft) of 300 Ohm tv twinlead

cut it into 2 1.5 Meter lengths (4.5 ft)

strip the ends of both pieces 3/8 inch.

join the ends of one piece.

cut the center of the piece with the joined ends.

strip those wire back 1/4 inch

connect each wire to the each wire on the end of the other
length of wire.

connect other end to reciever.

thumbtack antenna to wall

your 300 Ohm folded dipole should look like this:

```
_____________________________________________________
/ \
\_______________________ _________________________/
| |
| |
| |
| |
Connect these
leads to your reciever
Use Balun if necessary
```

>
>Ryan

If the remaining winding is rated for the current the radio will draw, it should make a good filter, but its upper frequency would be limited. I'd guess that a typical power transformer would take care of stuff into the low HF range. It should do a good job of attenuating spikes from the ignition system.

If the secondary is shot, you could rewind it. It's not hard to do, and you could use it for a 12 volt supply, battery charger, or whatever depending on its size and your needs.

Hi-

I'm looking for some radio gear for winter projects.

In the vacuum tube arena:
Geloso (anything)
TMC (Technical Material Corporation) GPR-90 and SBE-2
Any homebuilt ham or shortwave gear.

Solid state stuff:
ICIR, Cubic, Stoner, Alda, Atlas, Astro, any other early solid state
(Hammerlund, National, etc. also)
Any homebuilt or shortwave gear.

I prefer radios in need of work and priced accordingly but will
look at anything (especially Geloso and TMC!)

Have cash, radios, and datacom gear to trade.

Dear fellow,
As a part of a research programme carried out in the Computational Vision Group at the Dept of Computer Science, University of Reading, UK, a visual perception test is being circulated via Internet, the result of which will be used in my thesis (and be sent to you if you so wish). The test contains a number of images which you are requested to interpret. I would be grateful if you could spent a short time (less than 10 min) to fill in the form/questionnaire for this test which is provided at my Web page at the following URL:
http://www.reading.ac.uk/~ssrmrouh/surv_tst/HTML/psy_tst1.html

Thanks in advance,

Behrouz M-Rouhani,
Research student in CAD-based vision, Dept of Computer Science, Reading Univ., UK

1235. FS:12V Pwr Plug:Ken, Icom,Yae,Alinco

Message-ID: <1996Sep16.201242.2088632@undefined>
Source record: 102465

I have found a source for those DC power cord plugs. The ones I've got
have 6 pins, male plastic with metal female inserts.

These plugs fit most 12VDC HF radios:
Icom 735 and alike, newer Yaesu and Alinco DX70.
Kenwood TS-120, 130, 140..430, 440, 450..850..TS50, 60, 660, 670..and alike.

Make your own power cord yourself, YOUR WAY!
Crimp or soldered, long or short, heavy gauge, purple with polka dots...

I'm offering the 6 position plug with 6 inserts for $4 each,
or a deal 3 for $10. All prices include postage in the US.

To order, kindly send a check to:

R. Langston
286 Hudson Street
Cornwall-on-Hudson, N.Y. 12520

You can also email me for info at: n2cjj@ibm.net

It's a great deal if you use one rig at home, in the car and at work and
are stuck dragging one power cord all over...

I still can't believe AES and others get $30 for a power cord.

1236. Re: Why we build - Homebrew advantages of CW

Indeed. My article spoke of my support for CW in the context of why and what to homebrew. Some have skewed the argument into something else.

>
> ...<SNIP>

There is some confusion here (perhaps on my part). IFAIK, there is no requirement for me to take my homebrew TX down to an FCC test site and have its emmisions checked. Of course, that does not mean I don't have to meet the emmisions standards.

WRT the ease/cheapness of including a microcontroller on the TX - nevertheless, you have increased the complication substantially. How easy is it to implement a digital encoding scheme in addition to the extra HW design and construction? What of the potential interference of the 40W emmisions right next to the digital electronics? Again, this has made the low level homebrew entry point substantially more difficult. If you were to say, "use an off-the-shelf controller board and/or already written software", we're back to the modular approach and increasing cost.

WRT CW, it seems to me some people spend more time worrying about the CW test than it would take to study and do it. Unlike what someone else said, it is nowhere near as difficult as learning another language. And many, in their zeal to hammer the requirement, lost site of the context in which I framed my argument for the test (ie, the ease of homebrewing a CW TX).

I still maintain there is no easier low level homebrew entry point than a CW TX. Just do the CW test - it's easy (easier than trying to get it

eliminated). Complaining that you're being forced to learn something is, IMO, immature. Anway, if the CW test is too much bother, I imagine that homebrew design and implementation would seem a terrible waste of time when one can go and buy a radio.

The throughput efficiency of CW is not of great relevance, it is more the bandwidth PER USER that is of importance (unless one propose that we be forced to use concentrators or have strict time limits). CW uses very little in the way of spectrum. Anyway, I'll bet most who complain are interested less in efficient digital modes than in simple bandwidth consuming phone (I have no proof, but it seems logical, given their reluctance to learn something as simple as Morse). I bet most homebrewers are more interested in getting on with it than they are in bellyaching about the unfairness of the CW requirement. To borrow a phrase from somewhere, "Just Do It".

If the complainers get their wish, next it'll be all those "irrelevant and discouraging" technical requirements on the chopping block, watch and see. That'd be bad news for homebrewers, IMO.

Cheers,

Chris.

1237. Strange balanced modulator design question

> Hz, before it is fed into a balanced modulator using four diodes.

Well sir, I have an Elektrisk Bureau HF exciter (from Norway), dated 1973
that generates
AM-USB, USB and CAM using a similar aproach:

1) The mic amplifier have a "several" dB per octave low-pass filter at
2.600Hz.
2) This signal is applied to a balanced modulator which have a 20KHz
carrier.
3) The "SSB" filter is a 19.7KHz low pass filter that just lets pass the
20KHz LSB signal.
3) As professional xmtr like this, it has only USB/AM-USB at the output.
The four PLLs
sum/differences places the audio signal on it's spectral USB position.

To have LSB, what I did: another balanced modulator, with a 3.0KHz carrier
and a
cascade of 2 op-amp filter, in a 7th order filter each, cut-toff abt
2.6KHz. So I got
at this audio baseband the audio spectrum inverted - that's my LSB
solution. The only
problem I have is that I need to set the exciter 3KHz lower in frequency
when I want to
transmit in LSB. But the audio quality is impressive! Don't forget that my
original low-
pass filter in the transmitter helps to remove the 3300...5900Hz
sideband...

Find a copy of 73 for October 1989. On page 31 there's an article
entitled "Put your IC-22S on Packet" by Michael S. Dooley. Maybe
a local ham club has back issues. Or try 73; they might have back issues
and if not, I think they will photocopy the article (1page) for a fee.

Many thanks to Tom for posting this previously, I have used this list
to great
effect, and have looked-up mods for others posting requests here...but
I've
got other things to do, so folks, go hunt 'em down. For whatever
reason,
archie dosen't report many of these locations, so this list is a
necessity.

Now maybe we will see a reduction in redundant requests for mods?
If you don't know what this list is for, and you have a real (not just
UUCP
dial-up) internet connection ask someone who knows about "anonymous
ftp"

Even if you only have a dial-up, most listservs honor e-mail requests
for
files--if you know just where they are directorywise.

Ciao,
Michael Dahl
Again, thanks Tom!

I bought a bunch of junk from a old ham years ago, included was home made ladder line, using spreaders from tube and spool wiring, I remember the homes I grew up in used them. You may be able to find an old electrician or hardware store that still has them, I think they are only about 4 1/2 inches though.

If you use wood, which I use 1/4" dowels for my fan dipoles, I drill the holes about 1/4" from each end, then lash cotton string around the ends to keep them from splitting, soak the ends with white wood working glue and heat them in an oven to dry out the moister. Then I soak them in floor varnish.

I have an ICOM IC-22S that I would like to modify for operation on the packet frequencies. I have seen reference to a mod for this.. involves changes to the synthesizer (new crystal? retuning?) to cover the lower frequencies with 20 KHz spacing.

Now that I need it, I can't find the details. Anyone know where this information might be. Anyone else who has done this mod?

It depends on your plate voltage. A dual primary transformer might work if you used the second primary as an output and either rectified it or ran it into a voltage multiplier of some sort. Damn, gotta use some of those modern rectifiers. Oh well, sure beats not getting a project done, then if you do find a plate transformer, just transplant it.

A digital solution to an analog problem is never a good idea. (Any Bob
> Pease, Pease's Porrige, fans out there?)
>
> KE1C Pat
You had to go and ask. I have some friends at National and we have been ragging on him for some time to get an e-mail address. His answer..."Why? I have enough mail already", or something close to that. Yeah, I read his column every month and I agree with him about 95% of the time. I'll get over to National and meet him face to face one of these days. I'm in the A.T.E. test business.

I just have to ask what crazed engineer thinks a processor will outperform a good tuned cavity. I have used cavities at UHF and I don't think digital has a prayer unless there is a cavity in front of it.

Bill Baka, no shortage of opinions .

Sorry, but I never would have even brought up the subject if I hadn't
accidentaly seen other posts in this newsgroup blasting JAN for poor
quality.
Don't blame me for trying to get some other opinions. I was kind of
lukewarm on buying all those crystals anyway, since I have been thinking
of building a 500khz stepped synth instead of the crystals. Still, its
nice to have the rig working in the original manner. Again, sorry if I
offended you in some way. Rob.

1261. _In_Marconi's_Footsteps::_Early_Radio_ More info...

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-17 00:00:00 UTC
From: nyoung@nova.wright.edu
Message-ID: <1996Sep17.114118@nova.wright.edu>
Source record: 102478

A couple group readers asked me for more information about Peter Jensen's book, _In Marconi's Footsteps: 1894-1920: Early Radio_. Well, here's the info from the inside front page:

ISBN: 0-86417-607-4. (No LoC number)
Publisher: Kangaroo Press Pty Ltd
Addresses: 3 Whitehall Road
Kenthurst NSW
2156 Australia
-----or----
P.O. Box 6125
Dural Delivery Center NSW
2158 Australia
Publication date: 1994.
Cost (US$): $39.95

In a family where the coffee table is used for something other than stacking the youngest son's school clothes, this book would probably qualify as "coffee table reading." I think that's mostly the fault of the design & page size (176 pages, 8.5x11 inches, cloth cover with dust jacket). However, the book is much more than a table covering itself. The information is well-researched and the writing is excellent. The photos often show "then & now" comparisons and the technical drawings are completed with care and attention to detail. If you're the kind of person who wants to know what it was like to play with coherers or Perikon detectors, this book is a good starting point. Once you've read it, you'll with that Modern Radio Labs still carried all the neat stuff that ol' Elmer Osterhoudt did when he was among the living. But then, MRL is still alive -- though under different management -- and there are lots of crystal set loonies out here in the space between terminals & modems.

I for one have had very poor results with JAN crystals, but it was years
ago. I tried using them in a Marine and Two Way radios, they were more
often than not off frequency and drifted around. This wasn't a few
crystals, it was a lot of them and for common stuff like Micors.

I went to ICM, bigger bux$$$$, but they were much more stable and always
dead on.

Things can change over time but my experience, and the experience of other
people in the same line of work at that time, was the quality was not
there. I've never tried them since that time.

Obviously some other are still experiencing the same problems, and other
are not. Perhaps it depends on the end environment or the particular batch
of product.

>bchadwi@bsu.net

This is kind of a broad question, not knowing what kind of UHF
rig you have, but anyway, there were some ideas in the very old
'70s vintage ARRL VHF/UHF manuals that talked about high level
AM video modulation of older FM rigs. You might start there.
You should know that what you will end up with is double sideband
video, approx 9MHz wide, on the UHF band unless you do some
vestigial sideband filtering at the output of your TX.
Make sure you are not going to bother anyone, or do the filtering.

I have found that the cleanest way to generate VSB-AM TV is
to get a CATV headend modulator ($20 at hamfests) and drive
an upconverter or modified transmit converter to the desired
output frequncy. Make sure any power amplifiers you use
after the upconverter are true class A. Not the amateur market
junk that use class C transistors with Mickey Mouse bias or
you will have double sideband again!

Good Luck,

Have I misunderstood? Are you suggesting that the fact that you had to do a Morse code exam caused you to enter the hobby? I guess what you meant is that your interest in homebrew CW got you interested.

Having a Morse exam does not mean that there will be Morse operators out there - many people forget Morse soon after passing the test. It is the fact that some people LIKE Morse that ensures there are Morse operators, not the exam.

The reason for including a topic in a licence examination should not be based on a person's, or group of people's personal interests. It should be based on what the licencee is REQUIRED to do, or continue to know, AFTER the exam has been passed.

To illustrate my point, if an amateur uses a transmitter outside of the band, or builds and operates a piece of equipment which splatters over the band, there are provisions to penalise the amateur by fines and/or loss of licence. Thus, it is appropriate to have regulations and radio theory examined.

Now, what can happen to an amateur who uses Morse code poorly (slowly with lots of errors)? Are there licence implications? Can the licencee be fined or have the licence revoked? If the answer is no, then there was no point in examining the person in the first place.

A licence exam is used to define what a person should know and be able to do and is the benchmark for determining if the licencee is a fit person to hold the licence. This does not mean that the person cannot or will not forget what was examined, but it does mean that the licencee cannot use the excuse of ignorance if a breach occurs.

If it isn't important enough to have a penalty for non-compliance, then it isn't important enough to examine in the first place.

Mark.

There was a nice description in QEX, Sept. 1992 issue by Mike Gruber which might be fairly easy to build. It used a Sony AM-stereo chip CX857 and the phase shift network from Sony too, I guess from ICF-SW2010. At that time each of these was about $20.

You can use the Nat Semi LM1821 or LM1823 Synchronous Video Detector as a complete AM synch detector, although its not 100% optimal for this application. Chips contain vy sensitive IF amp, limiter, DBM, osc, phase shifter, etc. Parts are avail via NTE replacement also, so you don't have to neccessarily call Nat Semi if you're in big hurry. However, their sampling dept will gladly send you one for free, and as last resort, contact linear marketing, they generally will send to experimenters even if you don't have some big lie about being a design manager working on the latest HDTV revolution. :)

As the final last resort, contact Mr. Martin Giles who I hope still is Apps Director, and tell him "Mr. LM1893" sent you. Ha, ha, that should get you something- maybe disconnected. :)

Tell him all the ham circuits contain that wimpy Signetics NE602 IC and that you suspect its a piece of crap that Philips is expending their old Germanium wafer stock on.

Seriously, if you want a true super high performance design, send me a fax number and I will send you my synch sample and hold AM demodulator schematic using the SD5002 DMOS switches, VXO, MC1590 IF amp, 74ACxx DMOS drivers, ec.

Can use several of the Nat Semi synch video detectors for this, although
won't get ultimate performance. Couple are avail via NTE replacement, not
interested in rooting thru books, but think LM1821 was the earlier and
LM1823 the later. Can make almost complete circuit since contains high
gain IF, osc, DMB, phase shifter, etc.

If you can email me a fax number I can send you schematic for synch sample
and hold AM detector using DMOS switches, VXO, and MC1590 carrier amp,
that offers ultimate performance, way beyond one from old QST using NE602
and Signetics IF IC. I'm sure the old Signetics marketing people won't be
pleased, but whenever you see a 602, you can guarantee no-one has given
much thought to high performance.

You can use the Nat Semi LM1821 or LM1823 Synchronous Video Detector as a complete AM synch detector, although its not 100% optimal for this application. Chips contain vy sensitive IF amp, limiter, DBM, osc, phase shifter, etc. Parts are avail via NTE replacement also, so you don't have to neccessarily call Nat Semi if you're in big hurry. However, their sampling dept will gladly send you one for free, and as last resort, contact linear marketing, they generally will send to experimenters even if you don't have some big lie about being a design manager working on the latest HDTV revolution. :)

As the final last resort, contact Mr. Martin Giles who I hope still is Apps Director, and tell him "Mr. LM1893" sent you. Ha, ha, that should get you something- maybe disconnected. :)

Tell him all the ham circuits contain that wimpy Signetics NE602 IC and that you suspect its a piece of crap that Philips is expending their old Germanium wafer stock on.

Seriously, if you want a true super high performance design, send me a fax number and I will send you my synch sample and hold AM demodulator schematic using the SD5002 DMOS switches, VXO, MC1590 IF amp, 74ACxx DMOS drivers, ec.

>bchadwi@bsu.net

Well Bruce, may be U use any kind of high-level modulator
(at the vy. last PA amp and it's driver) that U find at some ARRL
handbooks (some use to have a 80mW 440MHz ATV exciter) but
remember that U will have a DSB signal: more bandwidht and power
waste.
I use to my tests a Jerrold CATV modulator, model S-450-M, that
can be set to generate a 445.25MHz video carrier on its standard
form. Mine is modified to extend this range a little bit higher since this
"agile" exciter is sometimes used as a IF modulator to 1296 and 2304
transverters. It's output level is about +55dBmV/75 ohm. The big
advantage is that this rig have a SAW filter that limits the video to
it's upper sideband. And it's spurious are avereage -60dBc!
So Ur UHF rig will be only the PA. And may be adapted to a kind
of class A amplifier, all amplification stages involved.

Regards ES GL.

Speaking for myself, if I hadn't been required to pass a 5 wpm, then 13
wpm Morse exam, I never would have known that I like Morse Code. FWIW.

> The reason for including a topic in a licence examination should not be > based on a person's, or group of people's personal inter=
ests. It should > be based on what the licencee is REQUIRED to do, or continue to know, > AFTER the exam has been passed.

I passed an exam that covered phone operating priveleges and digital
operating and theory. I am not REQUIRED to use these modes.

> To illustrate my point, if an amateur uses a transmitter outside of the > band, or builds and operates a piece of equipment which =
splatters over > the band, there are provisions to penalise the amateur by fines and/or > loss of licence. Thus, it is appropriate t=

the licencee > be fined or have the licence revoked? If the answer is no, then there > > was no point in examining the person in the=
first place.

I recall questions about Q signals on the tests. There is no penalty if
I do not use them correctly. Yet I do not believe you are proposing that
those questions be deleted.

Perhaps better questions to ask and answer is: "Is Morse Code still
relevant to the Amateur Radio Service? If so, should we retain testing
as a requirement for some or all amateur priveleges. Should we keep it
as a requirement in its present form? Why, or why not."

It is my personal opinion that Morse Code is important to the Amateur Radio Service for a number of reasons. The most important is that it is apparently important to a significant number (significant is not necessarily defined as a majority) of us. The alternatives proposed are important to a significant number of us, too, so those who are proposing solutions that do not consider the needs or wishes of others with alternative views are proposing solutions that are more divisive than useful.

Let's take followups to .policy, where they are more appropriate to the charter of the group.

I need a manual for an old Heathkit SB-110 6 Meter Rig. This is an old tube rig, and is currently in non-working, but otherwise good, condition. I am willing to pay copy and postal charges. The more info I get on this radio, the better, so if you have articles or other writings about the Heathkit SB-110, I would be interested in those also.

Thank you in advance for your help.

I need a bunch of vacuum tubes for a couple of radios that I am working on: a Collins KWM-2A and a Heathkit SB-110 6 Meter Rig. Some of the tubes that I need are as follows:

6U8A (Qty: 3)\
6EB8 \
6EA8 ---- These are "must haves"
6DC6 /
6AZ8 (Qty: 2)/

12AT7 (Qty: 2)
12AX7
6BN8 (Qty: 2)
6AZ8 (Qty: 2)
6146B (Qty: 5)
6CL6

If you have any of these tubes, let me know. I would prefer to purchase them all from one person, if possible, but I will purchase them from different places, if needed. If I could pick them up (local to Dallas/Ft. Worth, Texas, area), that would be a _HUGE_ plus. I will pay shipping costs.

Thank you in advance for your help.

>on me and tell me an easy way to build a makeshift antena that will give me
>pretty good reception until I can get a good one?

Go to Radio Shack and get one of their FM antennas made out of
300 ohm "twin lead". It's made of flat cable around 1/3 inch wide that forms
a "T" with the top around five feet across. You hook the bottom end of
the "T" to your radio and tack top to your ceiling so it is broadside to
your favorite radio station (in either direction). Very cheap.
The next step would be to get some more twinlead like the antenna
is made out of and extend the bottom of the "T" so you can put the top
as high as possible. If you could arrange for it to be above an outside
window (hopefully with a wooden frame) and get it "way up there" the
results will be worth it. Alternatively putting it up a staircase wall,
up inside an attic, etc would improve performance.

But you may mean that you need something VERY cheap :-) In this case go in
with friends who also need antennas and share the cost of some twinlead
to make the RS type antenna like this:

```
<------ 57 1/4 inch --------->
------------------------------
x x
-------------y y--------------
| |
| |
| |
| |
| |

\/\/\

| |
| |
z z
```

The top of the "T" should be 57.25 inches long for the middle of the
FM band. You simply strip and tie the two wires at each end of the T
top together at the "x" points, then cut one side in the middle and
tie the lower part of the T into place at the two "y" points. The

"z" wires go to your radio. You can study the antenna at Radio shack to see what I'm describing. This type of antenna is called a folded dipole.

If your radio lacks a pair of screws for attaching a balanced antenna but instead only has a round coax socket you'll have to buy or scrounge a 300 ohm to 75 ohm transformer that matches the socket directly or with a short length of coax. Most parent's homes have one or two 300 to 75 ohm baluns in the bottom kitchen drawer :-) If you find a tubular looking thing around 1/2 inch diameter and two inches long with a threaded socket on one end and a little piece of twinlead coming out the other, that's your man. Or the ideal would be the little oblong plastic type with two screws and a round plug that slips over a coax socket directly (RS should have these).

Pete

For some reason they almost never mention that it exists. My sister bought a new Mark VIII and it had AM stereo, but nothing on the brochure or owners manual mentioned it.

It's usually a programmed frequency, often that can be scanned "in the
background" while listening elsewhere (i.e., the radio occasionally
polls the "call channel" a few times per second looking for activity).

In Japan where all operations are 144-146 MHz simplex, the call channel
seems to be by default 145.000 MHz.

Even more of a piss-off point, some of the smaller
(like 100ma) types have a fuse built into them,
usually INSIDE the windings, meaning right up
against the core. So if the primary reads open,
count the turns when taking it apart. Might
merely need chucking out the fuse and putting
it all back together - good as new.

MIDWEST MOBILE MANIA!

The September 17 shootout was held at Mounds State Park in Anderson,
Indiana and was attended by 27 hams. A total of 13 mobile ham stations
were tested, some with several different types of antennas.

The measuring equipment consists of a two turn, 3 foot dia. "magnetic"
loop tuned to 3.875 MHz. The loop was grounded to the park water system
which eliminates the previously noted sensitivity to passers-by. The
received signal is rectified by a 1N34 into a small ceramic capacitor.
The resulting DC voltage is read by a 3 1/2 digit meter on the 1.999V
range.
The mobile vehicle was approximately 75 yards from the loop during the
test. Each vehicle was driven to place the antenna system directly over
the same spot (vehicle facing away from the receiving loop), and all
other vehicles were moved to a parking lot some 1000 yards distant and
the antennas dismantled (not resonant on 3.875).
The mobiles were restricted to 100 watts (measured with a Bird meter)
and a less than 6 foot mast under the coil (or resonant part of the
antenna). The resulting antenna had to be street legal (less than 13
feet and 6 inches tall from the ground) and reasonable to be driven at
highway speed.
We were mostly interested in what works better than what and not in who
"wins", but the spirit of competition was present (naturally).
The strongest mobile antenna system read .404 Volts with 100 watts and
read about .250 with 50 watts giving some sense of scale to the
readings. So someone (using 100 watts) with a .250 would be losing about
half his power compared to the best system measured (to something or
somewhere with respect to the receiving loop 75 yards to the rear of the
```

vehicle). We have noted in previous shootouts that the readings were nearly linearly proportional with power from 100 to 10 watts.

The results are as follows (I'm dropping the decimal point in listing the numbers). Unless noted otherwise, the bugcatchers had 5 to 6 foot, 1 inch dia. masts under the coils, some copper pipe and some stainless steel (not a significant difference here, but the four highest guys were with copper masts). The capacity hats were several feet above the coils unless noted. I'm listing the results by decreasing score for the first antenna tested by each participant.

TOM, W8NSF 404 center loaded bugcatcher style with two small foot long stingers at top of the whip arranged in a V (adjustable angle between them).

JIM, KJ9T 395 center loaded bugcatcher style with three film reel cap hats distributed along the whip.

JOHN, N8IYN 386 center loaded bugcatcher style, no hat, 3.5 in dia coil wound with #10 at 5tpi for 73 turns, approx 14-15 inches long (about 95 uH).

DICK, N9HLT 375 same system as N8IYN.
N9HLT 380 same system except 3 inch dia coil about 18 to 20 inches long, 95 turns of #10 at 5tpi, same inductance as the 3 1/2 inch dia coil.
N9HLT 401 shorter coil (that is, less inductance, about 75uH) with six, one foot long stingers half way up the whip arranged in a circle.

BILL, N4VMY 369 same as N9IYN

CHUCK, KE9UW 364 same as N9IYN (this is me)

GEORGE, K9PAW 360 center loaded bugcatcher style, aluminum mast, with 2 wire clover loops for cap hats.

BILL, KF8MV 318 center loaded bugcatcher with 2 inch copper mast under the coil with cap hat about 6 inches above the coil.

BOB, KA8DBJ 289 center loaded bugcatcher style with cap hat.

RON, KG8XM 285 center loaded bugcatcher style with cap hat.
KG8XM 315 screwdriver antenna (go figure...we think that the relatively poor scores for systems very similar to the best systems are due to less than optimum tuning for lowest SWR. All of the highest scores were with systems that had remotely tuned tuners essentially AT THE BASE of the antenna as opposed to matching coils at the base, etc. that may not be tuned perfectly to lowest SWR. We noted that a difference of only 5 watts (95 watts instead of 100 watts) resulted in a drop of 10 or so points or so in the reading. Nobody is saying that it matters to the guy you're talking to a couple hundred miles away, but for the purpose of finding out what antenna system component or configuration might be marginally better, it does. This particular screwdriver antenna has capacitor matching at the base and was carefully

adjusted for low SWR). Our remote tuners have a series capacitor to tune to resonance and either a tapped toroid (relays) at the input or a parallel capacitor to ground at the input of the tuner to adjust the match. The four highest score individuals have a parallel cap, the next two have a tapped toroid (T250A-25turns wound around twice with #10 teflon insul silver plated wire), and K9PAW has a parallel cap.

CHUCK, WD8PEI 280 screwdriver with two cap hats.

DAVID, N9TQA 191 screwdriver on a huge Winnebago (mounted pretty high up on the back window making for a short whip....he has a lot of longer whips but they are all bent). He uses closed circuit TV to adjust the screwdriver to the marks for each band.

BARRY, N9BS 125 Outbacker mounted on a 3 or 4 foot mast (Hmmmmm.)

That's about it.
Some other things were tried including a coil wound with litz wire which resulted in a reading of about 75% of what his solid wire (of the same diameter of wire as the litz) coil acheived (I coulda told him that but I feel better about SAYING THAT after I saw the results).
Also,a triangular mast (point up and next to the coil) fed in the center of the base (not any better than the single one inch mast).
Basically, we want to fine tune our systems and this shootout mostly showed us some ideas that do not work well and reinforced some that do. They are briefly that long masts are good (raising the coil up higher in the length of the antenna? or raising the coil up higher than the roof?).
Coils that are longer than they are wide are better than the high Q (twice as wide as long) profile (still searching for the optimum length to width ratio...somewhere between a center loading square coil and a helical wound antenna...the coil isn't a lumped element here...it's part of the radiator....what's best?).
Capacity hats do better, but not that much better if the coil is reasonably low loss (wire size and spacing, etc.).
Low loss remote tuners (capacitors, not roller inductors in series with the antenna) at the base of the antenna that acheive a low SWR between the xceiver (at the dash) and the antenna (at the rear or the car) are better.

The highest reading of the day was 414 with N9HLT using the six stinger cap hat at the very top of the whip and the shorter coil that gave him the 401. This setup was not very roadworthy however.

Hot Chili, Ritz crackers, peach cobbler with Lite Cool Whip, double fudge brownies, and a great moist cinnamon coffee cake were consumed in great quantities..... you're not surprised, are you?

We really don't think that we know enough about mobile antenna systems..... that's why we are doing this and why it is so interesting to us, so please comment (it's ok to be kind).

Ben, W9JQA intends to write this up in an article (with pictures) to send to QST to publish if they want it. I hope he does and they do.

BIG CHALLENGE!
Several of the guys (not me) suggested that we should get together with the west coast mobile guys. They (a couple of the best mobile systems from each group) could meet somewhere half way (Colorado?) and maybe the impartial club in that area could supervise a midwest meets west shootout (are there any mobiles in the east?).

1292. Trident TR2400 scanner info

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-18 00:00:00 UTC
From: mramos@originet.COM.BR
Message-ID: <199609182238.TAA15543@netra01.origin.com.br>
Source record: 102323

Thanks for reding this:

I have a Trident TR2400 handheld scanner that have the following
problem:

- from 500KHz to 1.570GHz it's OK...
- when I set the frequency to 1.570.001 the sensibility falls about
35dB!
- I tried a "CPU reset" as sugested by a U.K. equipment providor,
reprogramed it (and works!) but the 1570 to 2060 MHz SHF band
still with problems.

It's a strange coincidence but one of the "reprograming" procedures
told me to enter some command (i'll not describe all) like this
7 <enter> 1570 <enter> 2060 <enter> 749.265 <up><up>....

It's more or less obvious that we're telling the CPU in wich frequency
range it should use an "up-convertion" procedure, plus any PIN diode
filter switching to allow this 1.57 to 2.06GHz reach the front end!

This equipment is the same Camnis HST-50 or so... please, any mainte-
nance manual, service manual, CPU procedures...will help.

This rig is to be used as a 902/1296 monitor to my homebrewings and
as a GOES/Meteosat receiver at 1691...this is my problem.

Thanks in advance es regards.

Filip's web site is very well worth visiting. If you read sci.electronics.repair, even once, you're bound to see reference to it and for good reason. It is a source of truly useful information, and the site is Lynx friendly too! There is quite a bit about repairing various devices, along with some more general electronic information. It's the sort of site that deserves to be linked too, and if more people would look there first, we'd get fewer of those commony asked questions.

By the way, I seem to recall the idea of back to back microwave transformers as an isolation transformer was in Electronics Now (formerly Radio Electronics). I guess it gave some details to pad out the article, but the basic idea is right there. It was in recent years, though I don't remember what issue.

Butch, You may have some other tuner in mind rather than the Johnson. We have
two of the 1kw's here at AAR2usi-k2usa and they have split stator capacitors
and special tapped inductor with link coupling. Pretty hard to duplicate
with parts available today.
We especially prefer them to the pi arrangements you describe
because they are a bandpass type rather than a low pass. This has come in handy when we have
had two transmitters on in the same band as we did during the Desert Storm operation.
The ARRL handbook has designs for what you seek and I have seen ads in QST
for the roller inductors and other parts.

1299. AM sync w. high integration IC's

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-19 00:00:00 UTC
From: and@pacifier.com
Message-ID: <and-1909960008080001@ip129.pdx1.pacifier.com>
Source record: 102330

[This is response to older post about AM sync detectors, so I posted it out of thread so more people will read it.]

You can use the National Semiconductor (video synchronous detectors) LM1821 or LM1823 as synchronous AM detectors. I've done it but it didn't seem like the ultimate performance, although I admit more work might make the difference, especially if you call up the apps eng dept there at National. They would probably also send samples if you cant get them thru normal sampling phone number or marketing. They're always looking for some new apps for those old state of the art video chips now that there is no longer any consumer electronics industry in the US. Also, NTE makes respacement part. Motivation is that these parts contain high gain IF, agc, phase shifter, etc, etc. for $5.

If you are interested in making the ultimate performance synch AM detector, send me a fax number and I will send you a copy of my Synchronous Sample-and-Hold AM demodulator using H-mode DMOS detector, VXO, MC1590 carrier amp, etc. I would have liked to make this a mag article, but motivation here is at nadir. You will have to design new VXO coil and varactor ckt if you need IF other than 9mhz. Whole ckt is actually alot simpler circuit than title suggests and fits in my rcvr in 3x4" brass box with internal "dead bug" construction. Thanks to U. Rohde for suggesting MOS S/H detector having much higher S/N ratio than conventional designs.

All I ask is that if this info gets into some writeup you include credits on schematic. Thanks.

Have never seen it advertised, but these tubes could probably be recycled
if there was the $$ motivation. Call up Svetlana. They might have much
higher motivation for recycling. Doesn't seem like there is much interest
left in US in tube manufacture now that Russians and Chinese are getting
way up on the learning curve.

I think that you wish to be able to change the output power of a tube HF power amplifier by changing the primary transformer voltage of the transformer that supplies the tube's high voltage (plate voltage). You ask if you might use an autotransformer between the power-line voltage and the transformer's primary.

You must not use this method if any filiment voltages are also supplied by the transformer!

Depending on the class of amplifier (C, AB, B), using this method to make small changes in output power is probably ok. However, large changes in plate voltage will change the amplifier's characteristics and may cause problems.

If the problem is unstable voltage only when transmitting, then the slide transformer will make the problem worse.

If the problem is power mains that slowly change over a long time, or all the time are low or high, than a very BIG slide transformer will help.

The variable transformer must be very large, much over the size you think, or it makes on and off transmit voltage stability worse.

Cross-posted to:
rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.shortwave,rec.radio.swap

I have found a source for those DC power cord plugs. The ones I've got
have 6 pins, male plastic with metal female (barbed) inserts.

The plug fits most 12VDC HF radios:
Icom 720, 735, 706.. and alike, newer Yaesu models and Alinco DX70.
Kenwood-TS120, 130, 140..430, 440, 450..850,..TS50,60, 660, 670...and alike.

Make your own power cord yourself, YOUR WAY!
Crimp or solder, long or short, heavy gauge wire, purple with polka-dots...

I'm offering the 6 position plug with 6 inserts for $4 each,
or a deal 3 for $10. All prices include postage in the US.

To order, kindly send a check to:

R. Langston
286 Hudson Street
Cornwall-on-Hudson, N.Y. 12520

You can also email me for info at: n2cjj@ibm.net

It's a great deal if you use one rig at home, in the car and at work and
are stuck dragging one power cord all over....

I still can't believe AES, HRO and others get $30 for a power cord. HiHi!

Butch-

QST published an article entitled "Build a Dual-Differential Capacitor for Your Antenna-Tuning Network" in the October 1972 issue (page 22).

Essentially, this article describes how to get around the problem of locating the dual-differential cap used in the Matchbox design. It includes complete construction details [the rest of the components are pretty easy to fabricate] If you can't locate the article, let me know; I'll send you a copy.

The one between 7000 and 7300 would be of interest to those of use who
have old Hallicrafters HT-40's :) The cases on these can be taken
apart and new crytals put in them, although I have no idea who would
cut rocks for the 243 package any more. If you're looking to sell,
drop an email.

Source record: 102343

Have been playing with some various XTAL filter designs. I have Zverev's excellent standard, but would like to do one with more poles than in his tables, especially the gaussian and gaussian to -12 dB. Anyone know how to calculate the k & q values? I suspect I'm looking at the method in his book and don't see it, but with a Pentium Pro 200 and Mathcad, suspect I have more firepower than he used for his derivations! (Not the equations)

FWIW, have had a good time running thru some old data from published articles, in HR, Liao's amplifier book, some old vertical formulas and seeing the problems with rounding or smoothing in graphs.

>important to a significant number of us, too, so those who are proposing
>solutions that do not consider the needs or wishes of others with
>alternative views are proposing solutions that are more divisive than
>useful.
>

So the code should be forced down everyone's throats, because SOME
SEGMENT of the ham community views it as "important" (to them).

That makes ZERO sense, Ed ... how would the CW folks like it if the
digital folks forced a test in coding software algorithms for DSP on
them? After all, those skills are *important* to a(n ever-growing)
group of hams ...

Sounds like a *practical* test to me ... write some software routines
that implement an FFT, a Hilbert transform, do some digital modulation
and demodulation, complex filtering, etc. ... maybe even implement
some convolutional codes and a Viterbi decoder or two ... Would the CW
folks find this an appropriate *pass/fail* test element? (If not, WHY?)

I would submit that jaming things that they don't consider relevant down
people's throats will *always* generate some "devisive" feelings on the
part of the "jamee" ... yet that's what the code folks have been doing
to everyone for years and years ... and we're sick and tired of it ...
to quote "Network" ... "We're mad as hell and we're not going to take it
any more!"

If that's "devisive," so be it ... I guess we need some "dividing" ...
it's not always bad to stir things up a bit ... unless all you care
about is maintaining the status quo at all costs ...

1316. Expanding foam (urethane?) where to get?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-20 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDy0B0u.4L4@netcom.com>
Source record: 102347

I'm working on mounting several VHF radios into a ZERO/Halliburton type "suitcase" cabinet. I'd like to use urethane (expanding) foam to position the radios, instead of building some complicated metal structure (the radios are various ICOM IC-?02 series VHF/SSB rigs). Anyway, where do you buy the stuff? As I recall, it's two chemicals, and when you mix them, they make a foam that then hardens. You can form the stuff by pumping it into a heavy duty plastic bag, forming it around the equipment you want to package, and then let it harden. Then after it's hardened, you can cut it with a knife to make openings (for cables), adjustments, and such.

Anyway, is this stuff bought at hardware stores, paint stores, or where?

> 73 de Geoff, VA3FQA
> va3fqa@amsat.org

You'll have to get a piece about a foot long of aluminum tubing
that will fit over the cut one. A couple of saw cuts lengthwise
in the new piece ends and a couple of stainless hose clamps will do the
trick. Go down to your local electrical wiring supply house
and get a product called Alox or equivalent. It is a conductive compound
made for aluminum conductors and smear some on the parts before
assembly.
Stuff works great and also keeps out water from the joint . Have been
using it for many years. Two years ago we repaired a 30 year old log
periodic with the stuff and it brought it back to like new.

I have heard that Philips in Europe is big in this market, also worth a try are Motorola and Texas Instruments, plus a few lesser known manufacturers like Exar and Fujitsu (Japan). They exist, but you may have to go to a distributor and beg for one because they sure son't show up at Rat-Shack.

One point to bear in mind is that some countries only have "gentleman's agreements" about how the HF band works NOW. As long as the bandplan has the general agreement of amateurs, then it will be followed.

Mark.

1322. AM Synch det. sch. sent out

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-20 00:00:00 UTC
From: and@pacifier.com
Message-ID: <and-2009960055430001@ip138.pdx1.pacifier.com>
Source record: 102353

Got about dozen requests to previous post about offering to fax out schematic for my DMOS S/H Synch AM demod ckt.

Sorry if that one guy (name withheld) got about 15 aborted phonecalls, as I spent 2 hours tearing apart my XEROX fax machine and cleaning rollers, etc with alcohol (should have drank it instead).

Turns out I spent two hours screwing around trying to send out the first fax, not realizing the telephone line and phone line output connectors were reversed on back of fax machine. :) :)

Here have Power Mac clone worth more than my car, but is useless when trying fax out from hardcopy without scanner. Guess those days of cut-and-paste schematics are catching up to me.

As I was tired when first fax finally went out, tried to make cover letter to those whose fax number was obviously corporate #. Just sent single page drawing to the others. If you don't get your fax , email me again with more routing info, and I'll try to put together good cover page.

Rob.

You can find it in hardware stores in spray cans. Look for it where weatherstripping and insulation is sold. One of the brand names is Great Stuff Foam Sealant. It will take several cans to fill a suitcase, so buy plenty before you start, you don't want to have to redo it when you run short. 73 De Mark, WB9BVV

The Call memory may also refer to a memory channel,which is easy to access
with one button press (sometimes it may also be on the mic)

What WB0GAZ described is priority (which could be the same memory channel
os call).

There are 2 solutions to your problem:

1: Buy a scanner to recieve frequencies the '202 doesn't cover

2: Buy /build a convertor the convert frequencies to frequncies th '202
DOES cover.

Sorry there is no direct method to make the '202 recieve "out of band"

Source record: 102359

I am an OCXO designer, I have a quantity of unused oven Controlled
Crystal Oscillators (OCXOs) at 16.384MHz these units came on the market
very cheaply, no one else knew what they were;
I bought the lot.
Units are in metal boxes hermetically sealed with pins for PCB
mounting, I have an off air standard here and can calibrate ie ship with
information on what voltage to set to give frequency to +-0.1ppm when
you connect up.
This calibration should be good to better than 0.5ppm over the next few
years and 0.1ppm for a year or so.
Dimensions 75X50X30mm
These divide by 2 to the power 14 to give 1 kHz to function as the
reference for frequency synthesisers as used in instruments, radio,
cellular, TV Transmitters..
Oscillators are stable to 1 part in ten to the nine i.e. 0.001ppm.over
a wide temperature band.
Excellent spectral purity, measurement repeats to 0.0001ppm per
second.
Will operate over -40+70C
12 V supply 600mA on warm up. 1200mA when running@23C
Output 1.5 v Peak to Peak sinewave AC coupled, 50 ohms source
resistance.
Built in 8V reference so that fine frequency adjustment can be
carried out with external potentiometer.

These units are latest technology incorporating SC cut low ageing
crystals ageing rate reduces logarithmically and can be expected to
age no more than 0.5 ppm over the next 5 to 10 years, inital ageing
already complete as units are over 1 years old.
Units within +-0.01 ppm after 10 minutes perhaps better.

Sold at approx 10% of manufacturers price.

Supplied tested with connection diagram.
Plots of SSB noise measured on HP3048 available soon,
Simple synthesiser circuit diagram (using MC145151.2p) to convert to
10MHz for use as counter standard supplied if required.

1 off price from FP Ltd. $75. Post 1 or two units Swiftair registered
to US add $15 Please make $90 cheque or 55pounds sterling cheque to

->>books from 15+ years ago, everyone has always got a heathkit
->>something. Whether it be a transmiters/receivers all the way down to
->>test equipment. So it raises the question, what ever happened to
->>the heathkit co.??

Well...that's not exactly the reason. Heath was originally a homebuilt airplane designer that sold a few parts to build airplanes (Heath Parasol etc.). After WWII, Ed Heath found hundreds of thousands of oscilloscope tubes on the surplus market -- not the instruments, just the CRT. RCA at the time held the patent on virtually all vacuum tube circuitry, and every radio manufacturer in the world paid a royalty to RCA for the use of the vacuum tube patents.

Heath found, and truly so, that if you simply sold PARTS and not completed radios or instruments, then the final manufacturer of the "radio" was the one who owed RCA the patent money. RCA wasn't about to go out to Joe Belchfire's garage and ding him a dime for putting together an oscilloscope, so Heath started out life making low-cost test equipment kits.

Test equipment worked it's way into ham gear, then "hobbyist" equipment, and finally into mainstream electronics -- tv's, hi-fi, and so on. It is when Heath went up with a $100 kit against K-Mart with a $49.95 prebuilt stereo that they went belly-up.

Look at the last of the H'kit catalogs. Lots of computer, tv, stereo, and all the stuff you can buy down at Circuit City for half the price. Their ham and test equipment pages went down and down until they were little more than appendages of the catalog.

I feel honored in that Heath came out with an aircraft clock to compete with RST's clock about 6 months after we introduced our kit. I can only giggle that they used the SAME chip that I used in my clock and made the SAME inadvertent error in the circuit layout. Now I'm not saying that I was copied, but...{;-)

EIMAC rebuilds some tubes. I don't have the list of tubes that they
rebuild but at least the larger tubes such as the 3CX15,000A7 the
rebuilt one is about half the price. The part number is the
same except that it has an "R" after the normal part number.
I just checked a couple of weeks ago about this.

>calculate the k & q values? I suspect I'm looking at the method in his book

If, for the filter your want, you have the component values of
the low pass prototype, the k values are simply the reciprocal of
the geometric means of each pair of adjacent elements. The q
values are simply the loaded Q's of the end elements (X/Ro).
Compare the k and q values for a simple Butterworth with the
component values, and you'll see what I'm talking about.

1337. Mid Atlantic VHF conf & Packrats Hamarama announcement

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-20 00:00:00 UTC
From: landisj@nad.com
Message-ID: <1996Sep20.101552.645@main03>
Source record: 102368
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.swap

*** Mid Atlantic VHF Conference ***

The 20th Annual Mid-Atlantic States VHF Conference sponsored by the Mt. Airy VHF Radio Club will be held on Saturday, 5 October at the Days Inn in Horsham PA. Technical presentations relating to VHF/UHF/SHF weak signal operating will begin at 9AM.

The Days Inn is located just north of exit 27 (Willow Grove exit) of the PA Turnpike, just north of Philadelphia, in Horsham, PA. Rooms at the Days Inn can be reserved by calling 215-674-2500. Mention Pack Rats for a discount. The Days Inn is filling up quickly, so reserve soon. Additional lodging is available in the Horsham area: Holiday Inn Trevose (215) 364-2000, Marriott Willow Grove (215) 830-0550, Hampton Inn Willow Grove (215) 659 - 3535, Warrington Inn (215) 343-0373.

*** HAMARAMA ***

On the following day, Sunday 6 Oct. the Packrats will have their annual hamfest at the Bucks County Drive In Theater, about 5 miles north of PA Tpk. exit 27 on Rte. 611. Talk-in on 146.52 simplex and the club repeater on 224.58.

Ron, WZ1V has placed the flyer for the events, including a preliminary list of presentations, on the N.E.W.S. Group web page:
http://uhavax.hartford.edu/~newsvhf/hamarama.html

For more information on the technical conference or a possible presentation slot, contact John Sortor, KB3XG, at 610-584-2489 or at JohnKB3XG@aol.com.

** Preliminary Conference Agenda **

SPEAKERS TOPICS

KD1DU, Del Schier - Introduction to 10 GHz Equipment and Operation

WB6JJN, Jim -Amateur Satellites:Modes, Bands,& Issues @ VHF thru Microwaves

AJ3K, Jim Rautio, Sonnet Software - 3-D Planer Electromagnetic Design

WA1YHO, Gary Dallas - Using YO & AO to Optimize a 6M Antenna System

N1DPM -Introduction to VHF/UHF Weak Signal Operating

Harvey Kaylie, Mini-Circuits Laboratories

WB2SON, Richard Fiore - American Technical Ceramics

W3ZZ, Gene Zimmerman - 40 Years of Contesting

Preliminary schedule of events:

Friday, October 4, 1996
5pm to 11pm - Out of town guests arrive, check in.
The 2 meeting rooms be used as a hospitality suite. The Pack Rats will provide snacks & beverages

Saturday, October 5, 1996

9am to 12pm Morning conference session.
12pm to 1pm Lunch break
1pm to 5pm Afternoon conference session.
5pm to 7pm Hospitality suite.
7pm to 9pm Dinner/Banquet
9pm to 11pm Hospitality suite.

Sunday, October 6, 1996

6am to 10am Check out
7am to 3pm Hamarama at the Bucks County Drive In

73!
W3IIT & AA3GN
--
landisj@nad.com - speaking only for myself, of course
No, this is not a sig.

You can quote sales figures of parts being sold but you can't conclude
the projects those components are supposed to go into are ever completed
or even started. Sales of parts doesn't give a very accurate account of
homebrewing. But, hearing comments of what folks are building naturally
enough does gives an account of the general trend in homebrewing.

Now, I think we're going to have to redefine "homebrewing" - I've got
an article here from QEX titled The Ultimate VFO (April 1996); the
circuit contains two major ICs, a clock module, a handful of resistors,
and a few push-button switches. Is snapping ICs into sockets considered
homebrew? I'll say "no", and call something like this a kit, instead.
I'll snap it together but won't make any claim that I homebrewed a
VFO. I've homebrewed VFOs before from scratch and this project won't
begin to come close to the detailed work that those necessitated. And
it won't be as rewarding, either.

Message sender : and@pacifier.com

Got about dozen requests to previous post about offering to fax out schematic for my DMOS S/H Synch AM demod ckt.

Sorry if that one guy (name withheld) got about 15 aborted phonecalls, as I spent 2 hours tearing apart my XEROX fax machine and cleaning rollers, etc with alcohol (should have drank it instead).

Turns out I spent two hours screwing around trying to send out the first fax, not realizing the telephone line and phone line output connectors were reversed on back of fax machine. :) :)

Here have Power Mac clone worth more than my car, but is useless when trying fax out from hardcopy without scanner. Guess those days of cut-and-paste schematics are catching up to me.

As I was tired when first fax finally went out, tried to make cover letter to those whose fax number was obviously corporate #. Just sent single page drawing to the others. If you don't get your fax , email me again with more routing info, and I'll try to put together good cover page.

Rob.

There was a good article on building a discone antenna in the Sept. 87
issue of 73 magazine if you can find a copy, I can copy the article if
you need it. I built this design and it works great. It was fairly
inexpensive and used brass pipe fittings and brazing rods for elements.
No lathe required, just a decent drill press and taps. I spray painted
my antenna white after construction to weatherproof it as brazing rod
tends to rust over time.

Taking 5 minutes to read what follows can change your life :

I saw an article in an internet newsgroup telling me I could make $50,000 within a month for an investment of only $5.

I thought it was a huge joke. I spoke to my wife, attorney and friends about it, and they all agreed it was some kind of scam. I can't stand scams, because usually someone gets burned, and I didn't want it to be me. Of course, I rejected the idea at first. after a short period of about two weeks ,I thought : "I have already heard of such things. But on the Internet ?!?!? ". I decided that even if I had to throw $5 into the fire, I wouldn't mind it that much, and gave it a try .After all I needed a LOT more than five dollars.

Two weeks later, I began receiving money -- every day! I could not believe it! Soon, hundreds, and then thousands of dollars began to roll in. Within 4 weeks, I had received a total of $32,445! It came from everywhere in the world. My bank account has changed its "-" into a big "+" (++++)!!!,I bought myself a car and things I wanted for a long long time for my wife and kids!

If you follow the three steps below, there is no reason why the same shouldn't happen to you! This is a legitimate investment opportunity. You invest $5, and you receive a return on your investment. So does the next investor. NOT ILLEGAL, NOT A CHAIN LETTER- PERFECTLY LEGITIMATE.

If you are not interested, then don't participate, but please print this article and pass it on to someone who may be interested, so they can take advantage.

The procedure is simple: 1) Write your name and address, an e-mail address, and the name of the newsgroup where you learned of this on 5 sheets of paper. Below that, write the words, "Please add me to your list." Fold $1 note or bank draft or money order in each piece of paper and send them to the following 5 addresses.:

1. Oleg Gorbik,
10834-97 St.
Edmonton, AB, T5H 2M3 CANADA

2. Nir Levi,
PO BOX 342

Yavne, ISRAEL

3. Landon
#1 Lakeway Drive
Conroe, Tx 77304 USA

4. Olivier Arcadipane
237 rue Francois Andre
7390 Quaregnon BELGIUM

5. Beyond Technology
5641 Apgar Street
Houston, Texas 77032 USA

2) Now remove the top name from the list, and move the other four names up. In other words, #5 becomes #4 and so on. Put your name as the fifth one on the list. Use a simple text editor such as Notepad, in your "accessories" window (If you have MS-Windows),or DOS editor. In fact, any editor will do.

3) Post the article to at least 200 newsgroups. There are 17,000, so it shouldn't be hard to find that many. Try posting to as many newsgroups as you can, and the bigger the newsgroup is, the more people are to see your message!

You are now in the an order services business, and should start seeing returns within a week or two. Of course, the more newsgroups you post to, the greater your return is. If you wish to remain anonymous, you may use a psuedonym, call yourself "The Manager", "The Boss", whatever but make sure your address is correct.

Now, here is why the system works:

-Of every 200 posts I made, I received 5 responses. Yes, only 5. You make $5 for every 200 posts with your name at #5.

-Each person who sent you $1 now also makes 200 additional postings with your name at #4. ie. 1000 postings. On average therefore, 50 people will send you $1 with your name at #4. $50.

-Your 50 new agents make 200 postings each with your name at #3 or 10,000 postings. Average return 500 people = $500. They make 200 postings each with your name at #2=100,000 postings=5000 return at $1 each=$5000.

-Finally, 5,000 people make 200 postings with your name at #1 and you get a return of $50,000 before your name drops off the list. AND THATS IF EVERYONE DOWN THE LINE MAKES 200 POSTINGS! Total income in one cycle=$55,000.

From time to time, when you see your name no longer on the list, you take the latest posting that appears in the newsgroups, and send out another $5, and put your name at #5, and start posting again. Remember, 200 postings is only a guideline. the more you post, the greater the return.

Lets review why you should do this. THE ONLY COST IS $5. Anyone can afford $5 for such an effortless investment with such SPECTACULAR RETURNS.

Some people have said to me, "what happens if the scheme is played out and no one sends me any money? "Big Deal, so you lose $5-but what are the chances of that happening ?? Do you Realize that NOBODY cares for the LEGAL chance of winning such a BIG money as 50,000.00 $$$$???? and all for a microscopic investment of five separate dollars? just think of all of the new Internet users that join the net every day!!!

There are millions of internet users, and millions of new net surfers every month !!! This is the great plus of the Internet, people all over the world can hear you and listen carefully if you talk reasonably. Everyone will take that chance ! I agree, If it wasn't the Internet, and was a small circle of people, the chance wouldn't have been so small. the amount of money had to be 200 times bigger, and the chances were zero. It wouldn't succeed.

But here, on the Internet, it is a giant village, where new thousands of members join in every day ! you CAN'T lose !!!!

Remember- read the instructions carefully, and play fairly. That's the only way this will work. Get a printout so you can refer back to this article easily.

Try to keep a list of everyone that sends you money and always keep an eye on the postings to make sure everyone is playing fairly. You know where your name should be.

REMEMBER-HONESTY IS THE BEST POLICY. YOU DO NOT NEED TO CHEAT THIS IDEA TO MAKE MONEY!! BESIDES,NOT PLAYING THE GAME FAIRLY IS ILLEGAL.SO LET'S BE REASONABLE AND PLAY FAIRLY,SO WE CAN ALL ENJOY THE INTERNET GOLD MINE.

GOOD LUCK FOR YOU ALL, And remember, play fair and you'll win, I don't want to mention what might happen to those who won't. AND AGAIN,SEE YOU NEXT TIME WITH SOMETHING YOU WANTED FOR A LONG TIME !!!

When the grid goes positive it collects electrons which then
makes the grid more negative. The result is the grid voltage follows
the peak positive value so the sum of the input and the negative
grid voltage is near zero.

The old tubes did not have a good vacuum and the grid leak had to
be selected to match the tube that was in use. They were some
times arranged as plug-in units.

Well said, Carl. I agree 100%. The trouble is though, things will
never change as long as the CW loving ARRL is running the show.BTW, I
resigned from that lofty organization last year just because of their
assinine stand on code requirements. And for the "Try CW, You'll
learn to love it!" group, I say "Nuts to you." I worked on that damn

Morse Code until it made me sick. It's still just noise to me. Now I'm forever locked out of the HF spectrum because of this discriminatory rule.

jwg6@cornell.edu (Joel Govostes) writes:

<...questions about grid-leaks removed...>

I've always found grid-leak biasing a little mysterious myself, maybe due to the different explanations I've read, but I'll give it a try:

The reason a grid-leak detector detects is that it is operating near the plate-cutoff "knee" of its curve, so the positive half-cycles of the incoming signal produce a greater increase in plate current than the negative half-cycles decrease it, resulting in an output that more-or-less follows the modulation. The purpose of grid-leak biasing is to automatically bias the tube into the knee region. With a theoretically perfect diode such biasing wouldn't work -- the grid would bias itself to the level of the incoming signal and no more. However, due to the impact of electrons travelling to the plate upon the grid, grid current flows in a tube when the grid is still slightly negative WRT the cathode. This one-way current flow "ratchets up" the negative voltage on the grid condenser (keeping with the old terminology) until, with the reduced plate current and the increased grid-leak current caused by the higher negative grid bias, an equilibrium is reached. This point depends on the tube and the grid-leak resistance chosen. The time constant of the grid circuit is typically on the order of 100 uS (e.g. 50uuF, 2 Mohms), so the grid voltage can change fast enough to follow the signal modulation.

Hope this sheds more light than heat...

(BTW, there's a mailing list for tube homebrew called "glowbugs". Subscribe by sending the message "subscribe" to listproc@theporch.com and join in the fun.)

Before you connect the supply, blast the board with spray cold. (It's Freon in a can -- you can get it at an electronics supply store.) Spray the board until it's frosty. Then when you hook up the supply, look for the place the frost melts.

The method I've used with the most success with shorted ground and power supply planes is to drive the shorted areas with a signal generator at about 50 kHz, then sniff around with a physically small inductor of several hundred turns on a ferrite core hooked to a 'scope. The AC current will follow a more-or-less straight line from the signal generator to the short and back. At 50 kHz, the signal will penetrate outer planes reasonably well, so it works even for inner planes.

1348. Grid leak in simple rcvrs (???)

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-21 00:00:00 UTC
From: jwg6@cornell.edu
Message-ID: <jwg6-2109961018530001@cu-dialup-1019.cit.cornell.edu>
Source record: 102241

I have a question about the grid-leak in a triode receiving tube such as was used back in the 20s/30s.

Say you have a triode and are using it as a detector. The antenna is coupled to a L/C variable tuned (parallel) circuit. This tuned circuit connects across the input of the triode, grid to cathode. Now the antique radio books show the connection to the GRID as interrupted by a grid-leak capacitor. Across the capacitor is connected a resistor of high value.

I don't understand how this detects. From what I can see, you want the grid voltage to vary at audio freqhencies, so that the plate current on the tube will also vary at audio frequencies. Then the output of the tube drives the headphones with the original AF modulation that was "riding" the carrier at the transmitter.

How does the grid-leak capacitor+resistor cause the grid voltage to vary in this way?

When the tuned-circuit/antenna side of the grid-leak capacitor is "+", then the grid-side of the capacitor is "-". (At this point electrons are being removed from the grid to the nearest side of the capacitor). So now the grid is more positive. The plate current increases.

During the next half-cycle (rf), the tuned-circuit/antenna side of the grid-leak capacitor is "-". Electrons leave the grid-side of the cap and are forced back onto the grid. Now the grid is more negative. Plate current decreases.

What does the grid-leak resistor do, in the meantime? When does the capacitor discharge across it, and how does this accomplish detection? Over a period of time it would seem that the grid would get more and more negative and eventually cut off plate current. How do you "know" when the grid-leak-capacitor will discharge thru the resistor???

Thanks for any help on this. It is very fundamental, but the books I've found don't explain very well what's going on, and how you can get away without using a grid bias battery. 73, JWG

1349. grid leak ? part II

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-21 00:00:00 UTC
From: jwg6@cornell.edu
Message-ID: <jwg6-2109961030350001@cu-dialup-1019.cit.cornell.edu>
Source record: 102242

Forgot about my other question:

When the tuned-circuit/antenna side of the grid-leak-capacitor is "+",
then electrons rush from the grid onto the nearest side of the capacitor.
Doesn't this make the grid itself less negative, and cause grid current to
flow??

The books say that such a detector produces little or no grid current.
Seems to me that every other half-cycle of the input signal would cause
grid current to flow (electrons being attracted to the grid itself).
Thanks for any help on this, JWG

Computer power supplies can light up a car headlight without shutting down.

I would cut the 5 volt supply wire and insert that or a 12V 5A halogen bulb in series.
It will feed enough current into your short yo can

1- Feel around the board for an overheating chip and

2- mesure a few millivolts on your 5 volt shorted line:
when it says 0.00 milivolts you must not be very far from your short!

I think the reason that the nuts are listed as brass is because brass is easy to solder to. I don't have the article, but I assume the nuts are fixed in place for ease of assembly. If you can't solder them in place because they are made of something that can't be soldered to, then you'd have to use something like glue to hold the nuts in place, and that would not give a good electrical connection, which might be desired for shielding purposes.

If you have problems finding brass nuts (I've never looked for them), try a hobby shop. I've bought brass tubing and small pieces of brass sheet there for various homebrew purposes.

Well, they basically priced themselves out of the market. Why would you spend a lot of time building equipment that wasn't as good as stuff you could buy off the shelf for less?

The reason kits were made in the first place was because hams liked building them, and minus the labour of assembly, they could be sold cheaper than ready built items. (And hams were always...errr frugal)

By the 1970's there was no longer any financial advantage in kits.

If all else permits.... connect a current controlled DC power supply
across the rail (to gnd). Apply as much current through the rail as it
will tolerate without damage *a welder might be a bit unreasonable :-)*
Meassure voltage drops along the rail and perhaps you can detect where
along it's lenght the short is.

We learned about 10 days ago of a proposed new law in the State of Washington that would have required certification of all mobile radio installations by the State Patrol. We contacted the State Patrol and our state representative, Brian Thomas. As a result, the proposed draft has been thrown out and the scheduled public hearing on the matter has been cancelled. Today the State Patrol has advised us of new wording for the proposed rule - wording that no longer appears to have an impact on Amateur Radio operations. You can read the complete story in an EXCLUSIVE story published at Ham Radio Online at http://www.hamradio-online.com

From: j.r.isom@ieee.org
Message-ID: <51vrla$lgr@camel3.mindspring.com>
Source record: 102376

I'm in the process of building the RF attenuator shown in the 1995 ARRL handbook to use for foxhunting (the one made with double sided PC board and switches, not the active one).

If anyone else has built this device, maybe you can answer a question for me. The instructions say to soak the switches in acetone to remove grease. Does this mean to actually immerse the whole switch in the acetone? If so, for how long?

Also, the plans say to solder brass nuts inside the enclosure to screw the screws into. Is it critical that these are brass & not some other metal?

I would appreciate any help.

>Thanks for any help on this, JWG

When the grid goes positive the grid collects electrons which then
makes the grid negative. The result is the grid voltage is amost
the same as the input peak voltage.

Also many of the old tubes did not have a good vacuum. There
was some grid current due to the gas. Because of this most grid
leak resistors were plug-in so the correct value could be used
to match the tube used.

1372. simple "SSB" QRP transmitter, about 50mW diagram in ASCII

Newsgroup: rec.radio.amateur.homebrew

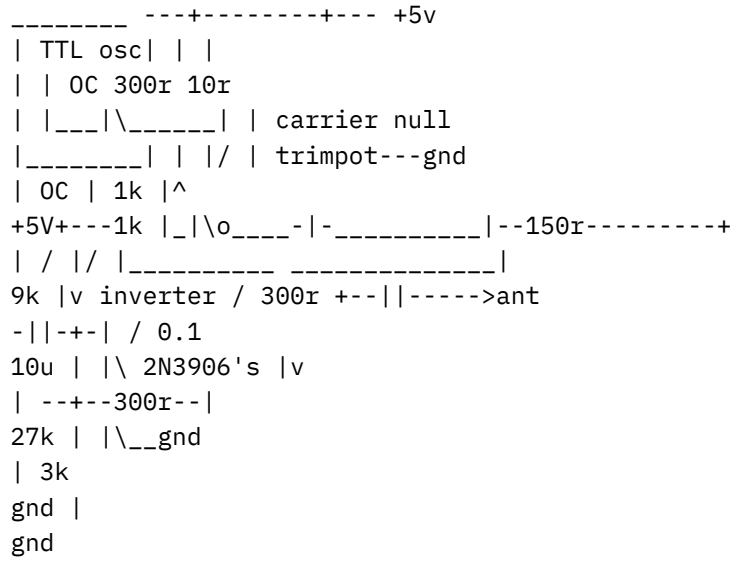
From: wa2ise@netcom.com
Message-ID: <wa2iseDy40p9.G4J@netcom.com>
Source record: 102254

QRP sideband (double sideband, "both USB and LSB recievers will hear it correctly") transmitter. Approx 50mW.



Being QRP, the wrong sideband isn't likely to QRM anyone, and harmonics too weak to worry about.
OC= open collector, like a 7407. One above is an inverter, the other is not. Cascade 2 inverters to create a non invert, use a 300 ohm (approx) on the output of the first of the inverter chain, use seperate inverter than the one driving the trimpot. Audio feeds the 10u cap on the first 2n3906 (pnp) transistor. You'll need a mic preamp. Adjust the carrier null trimpot to null out the carrier, listen on your SSB radio until the whistle (from the BFO beating with the carrier) goes away, too far and it comes back.

wlfuqu00@service1.UKy.EDU (William L. Fuqua III) wrote:
> EIMAC rebuilds some tubes.

So does Econco and Freeland Products. But the 8877 uses an oxide-coated cathode, not a filament. I am unaware of any company who rebuilds a tube with a heater structure that small. It would probably cost as much to rebuild a tube that small as it would cost to replace it outright.

I have never seen an open heater in one of these tubes that had an intact seal; they've usually gone to air and been destroyed internally. You also rarely see an open filament unless a tube has gone to air because of a cracked seal. In either case they're non-rebuildable since the structures inside are destroyed in the "fire."

Just as an aside, rebuilding involves recarburizing a filament structure. Methane gas is introduced and the temperature of the filament is run very high. The surface of the filament is converted by this process to di-tungsten carbide which is both very fragile and a terrific electron emitter.

WOW, great suggestions from you ALL! Thanks! Here's some additional info
that I left out regarding the shorted equipment VICTIM, which is a 2GIG
SCSI hard drive. I plugged it into my PACKET computer one day, and it SMOKED
the drive and shorted out the +5volt rail. I checked the voltage out of the
supply with a DVM and +5v/+12v checked OK. I suspect high ripple was the
culprit that killed the drive, tho I haven't checked it with a scope. I have
since replaced the computer case/power supply rather then wasting time
trying to debug an el-cheapo switching supply. System now works fine, drive
still dead. Due to the fine traces and sensitive nature of this drive, I am
leery of injecting BIG CURRENT into it. I DO want to make this drive WORK!

The SCSI drive is mostly surface mount devices on the underside of the PC
board, and I believe the smoke came from the top side (underneath the sealed
mechanical drive housing). I believe it was a 'smurf-mount' component that
died, smelling like a resitor. I hope NO active IC's were destroyed!

I especially liked the suggestion from Leo, PE1RHX, to use an AF amp and
inject an AF signal into the shorted rail and monitor along the rail with
a discarded cassette tape head til the sig stops (@short). This may be hard
to do on a multi-layer board with 'smurf-mount'. I may try it.

Well, I haven't tackled the trouble-shooting job yet...so please keep those
cards/letters and suggestions coming in. Best suggestions gets an honorable
mention and big thanks from ME, as well the satisfaction that YOU helped out
another ham in need. THAT plus $0.80 will get you a coffee ANYWHERE! Thanks!

Keep Suggesting,
Bill-WB9BBC

>
>I don't understand how this detects.

The tube self biases itself. As the cathode emits electrons, some of them
hit the grid. The very high leak resistance allows the charge to build up,
until the tube is very close to cut-off. Then the cathode reduces electron
emission, and the system is "in balance".

The tube is hanging right on the edge of plate current cutoff, in a very
non-linear region of operation. Any slight positive grid voltage through
the low RF impedance grid capacitor rapidly increases plate current, while
any negative voltage rapidly drives the tube into cut-off.

This is what you want, because the tube acts like a diode detector with a
VERY high input impedance and gain. The higher the anode load impedance,
the greater the gain.

The capacitors job is only to provide a low impedance path for the RF. It
can be almost any value, so long as it is lower than the grid input
impedance at the operating RF frequency, but the ideal value (maximum
sensitivity and minimum hum and noise coupling from the input) is where
the reactance is a few percent of the grid's input impedance at the
operating frequency.

The grid MUST be driven by RF and not audio, and the non-linear operating
point makes the tube respond to the positive signal peaks MUCH more than
any negative signal peaks (non-linear operation).

I hope this explains the grid leak detector circuit. If I missed anything
or wasn't clear, let me know. I can go into more much more detail if
needed.

>WA3CMQ
I have two. The first is made from a length of 1-1/2" steel pipe (HEAVY!) U-bolts are used to clamp angle iron to the pipe at two places about 3 feet apart. A pulley is atached to a a pipe cap with an eyebolt at the top end. The pole is lifted above two rungs of the tower and then lowered so the angle iron engages the rungs. The details depend on the tower design. Mine is an old 1959 vintage Rohn #6 which is just a heavy duty TV tower. The rungs are stamped sheet metal and the thing is climbable. Not a spec of rust after 10 years in Illinois and 20+ in New Mexico.

The second is made from 4" aluminum tubing with fairly thin wall. The brackets are fastened similarly. The pulley is fastened to a bolt through the pipe near the top and part of the tubing is cut away to clear the pulley.

That is not a detailed design, but maybe it'll give you a few ideas. It doesn't have to be complicated, but be sure that it is strong enough. Test it at low elevation!

>

So you're stating that the use of *modern* parts like ICs means that
it's not "homebrew"???

What if I design the IC? (Something I do regularly at work ...) Does
that count?

What if I program the IC (as in a uController)? Does that count?

Or does it have to be solely discrete parts (tubes?) hand-wired between
nails pounded into a hunk of wood? (which is what you seem to view as
"homebrew")

We've already established that many, if not most, hams are not building
anything ... wouldn't getting lots of them building
(and debugging) ever-more-complex kits be a step in the right direction?

As usual, Jeff, your arguments are an outlandish mix of troll and
"traditional-eleteist" ...

>
>By the 1970's there was no longer any financial advantage in kits.
>
>

As a former Heath contract engineer I can give a little more insight on
this.

It is very expensive to make a kit.

1.) Many customers didn't follow instructions or solder or do mechanical
asembly well and required technical support. More so in later years as our
population became less skilled at building.

2.) The cost of labor and materials to "kit" the parts exceeded the cost
of foreign labor and materials to assemble the same item

3.) Less people had the time or desire to build anything, so sales
declined partially from that reason.. and lower sales drove up the
overhead and design cost in each kit

4.) Less income meant less money for engineering, and that reduced
allowable design costs

Heathkit dropped out because of the market, just as hundreds of other
manufacturers do and continue to do, as we all get spoiled by low cost
overseas products. There is no single reason for this and there was
nothing Heath could have done, it's just a combination of many things that
are changing in the world.

Heath made it a point to NEVER to copy a design. Even though they could
have copied products I designed for other companies Heath always
approached me (and others) with offers of payment.

Every company I work for does this, many people approach with the same
idea for the same product as we have on the back burner. That's why most
companies turn away outside suggestions.. they might have to pay for
something they allready are working on if they listen or look at something

someone else does.

>cost as much to rebuild a tube that small as it would cost to replace
>it outright.

Fred is exactly correct on everything he said. It's pretty tough to rebuild an oxide cathode tube, especially a small one. They might as well throw it out and start over.

I've only very rarely found an open filament in an 8877. The usual failure is a grid to cathode short caused by structural probelms or operation with sustained high grid currents. The second most common failure is loss of emission due to stripping of the cathode (high current demand with low temperature) or many, many hours of heater time.

While open filaments happen, they are the rarest of problems I've seen. In the products I'm associated with.

The photons beaming down from space / parasitic failure stuff is another bunch of hoo-doo.

This step usually isn't necessary. If you think /know that there is
grease on the contact surfaces of the switch, dunk the switch into
acetone and work the switch back-and-forth a few times -that should so
it.
>
> Also, the plans say to solder brass nuts inside the enclosure to screw

> metal?

Not in terms of the unit's performance, but brass is the easiest to
solder -just try to solder stainless !

Good luck.

>Any crystals in the 7000 to 7300 KHz range fall within the 40m band.

>KC5NG

But not these ones. See below.

>>I have a box of crystals .. 25 kHZ difference between crystals,
>>starting at 5700 KHz to 8625 KHz. What can they be used for
>>or modified for The crystals are in FT 243 holders

Most of these older type crystals, NOT being hermetically sealed,
yopu'll find won't even oscillate. Their fundamental freq's
are often way way down in the approx 500kc range, the rigs
they were used in multiplied them up to the freq stamped on
the crystal. (Lower freq rock was more rugged, used in tanks,
equip bound to get tossed around a little).

First make sure they oscillate, and besides "rubbering" them
with a small padder, another trick you can use to shift their
freq is to drill and tap a small hole in the middle of the face
plate, use a screw to increase SLIGHTLY the pressure on
the plates over the wafer itself. But I'm still betting that most
of them will be duds.

|>tnx fer advise.
Yes. I have done this. In the USA/United States/Estados Unidos, we call that an "AUTOTRANSFORMER" and you can vary the voltage 0-100% of mains/line voltage. In our case it will be 0-120V AC or 0-220V AC

This worked VERY well for me using a 7000 Volts transformer as the HT+ or B+ for my "amplificateur" homebrew!

So now it's "real" vs. "non-real" homebrewing, is it? I've said it before, and I'll say it again: in an era when appliance operation is the norm and most hams are baffled by coax connectors, I'm prepared to be lenient on the definition of "homebrew". I too have homebrewed VFOs from scratch. Both ones with JFETs in them, and ones with DDS chips in them. The DDS ones work better and are less hassle all around.

To muddy the waters, consider a DDS VFO I built. I bought a pc board from FAR Circuits to build a DDS VFO from an article in 73 Magazine. I designed and built (wire-wrap) a microcontroller interface board, and programmed the microcontroller myself. Is the net result homebrew? Damn right! And, yes, it *was* rewarding, despite (or possibly because of) the Qualcomm DDS chip, computer clock oscillators, multiple micro-controllers, assorted 74LS TTL, even an intelligent LCD display.

Just because the electronics industry is moving toward greater integration, with the attendant reduced parts count, reduced hassle, increased reliability, and so on, does not render new projects non-homebrew, just because they don't look like something out of a 1955 ARRL Handbook. You can buy a significant portion of an HF receiver on a chip - does using such a chip render a project less homebrew? Or does it show that the designer was smart, knowing what he or she could buy off the shelf, and using it wisely?

I've beeen playing with a Huff and Puff VFO the last little while - the VFO part is a standard JFET affair from _Solid State Design for the Radio Amateur_, while the rest is 74HC logic, with a computer clock oscillator providing the reference. Is it homebrew? Yes! Is it rewarding? Yes! Was it mysterious and incomprehensible to members of the local ham club Friday night? Sadly, yes...

The brass is used to facilitate soldering. Positioning the nuts is made easiest by securing them w/ a stainless steel screw while soldering. The solder will not adhere to the stainless and thus can be easily removed after soldering.
I would be careful w/ the acetone as it will attack ABS, and polystyrene, 2 plastics commonly used in switches.

Almost all modern switches contain plastic parts that can be
permanently damaged by acetone. I've haven't experienced
problems with grease below 1 GHz or so, but if you must remove
it, use a commercial spray degreaser intended for electronic
parts.

Inductors that are designed to carry large DC currents usually have an
air gap to avoid core saturation. Using an ordinary transformer core
(without an air gap) can have surprising effects if the core saturates
(generation of harmonics etc.)

>>
>>I don't understand how this detects.

Grids do not leak. Often this is confused with contact bias which was
used with a few low level audio amplifiers. Contact bias uses a very high
value resistor from gird to cathode between 10 Meg and 100 Meg ohms.
Grid leak detector is really detection by grid rectification. It is very
sensitive but has the disadvantage of loading down the preceeding tuned circuit.
The capacitor must be chosen such that it and the grid resistor have a long
time constant in respect to the RF frequency but short in respect to the
audio frequency. The grid conducts on the positive cycles and charges the
capacitor to
the peak value of the signal and it is discharged thru the resistor. You can
verify this by playing with the capacitor in the detector. Use one very
large and the audio will go away. If you use one too small in value the
audio will be attenuated somewhat.
Another common detector was the plate detector. It had a large cathode
bias resistor and placed the tube in near class B operation. The low pass
filter circuit was placed in the plate circuit so that only the audio would
be passed to the rest of the circuit. A low pass filter is often placed in
the plate of the grid-leak detector as well.
The plate detector has much lower sensitivity but a very high input
resistance thus reducing the loading on the preceeding tuned circuit.

From: louwers@stevin
Message-ID: <52607l$knu@frontier.tno.nl>
Source record: 102142

Hi there,

I am a fanatic amateur rocket builder. As our rockets get better all the time,
we start to get problems in retrieving them.

We think that recovery would be much easier if we had a kind of FOX
hunting transmitter in it. So we are looking for a _small_ transmitter
(144 MHz) design for our rockets. Range should be about 5-10 Km's.

Does anyone of you have a good design for such a small transmitter? Preferably
with PCB layout. Any help is greatly appreciated.

I hope this is an appropriate group.
I was wondering what the radar detector local oscilator
is at for a frequency. I have been trolling for taillights
and I would like a radar detector detector
I think the local oscilator is around 11 gHz or so but I
would like a better number....
thanks
Trent

1409. VHF Antenna that Looks Like TV Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-23 00:00:00 UTC
From: csmith1@ccgate.hac.com
Message-ID: <5262q6$nsg@newsroom.gsfc.nasa.gov>
Source record: 102144
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc.

I am looking for an article that is supposed to be in CQ, I think from
years ago. Bill Orr's book "Simple, Low-Cost Wire Antennas for Radio
Amateurs" has something called a CIA Special. This ant is designed to
look like a TV antenna, but is really a 6, 2 and 220 antenna.
It has 2 beams, stacked. Each beam has a pair of 6 meter dipoles in a vee
shape about 1/4 wave apart.

Anyhow, I got it to work on 6 meters using their suggested tuner design, but I
can't get it to work on 2 (3:1 SWR is best I can do).

I am hoping that whomever told me it was once in CQ Magazine is correct and
that I can get hold of copy of the article to get more info than I have in
the book to get it going on 2 meters.

Any help appreciated! 73 de Chris NR3O

>you spend a lot of time building equipment that wasn't as good as
>stuff you could buy off the shelf for less?

Heath had an initial advantage when the first started in that the wiring in electonics was point to point and very time consuming. When PCBs were used and the boards were stuffed and wave soldered by machine that advantage went away. Within Heath, the development for a kit had to be paid off in two years of production. This was the standard and that set the kit price (we had an old PDP-8 that was pre-programmed with the accepted formula to generate the kit price). The problem was the volume. The volumes were in many cases for Ham equipment a few thousand a year. Also throw into the barrel that their was not a lot of money for test equipment. But.... it was a great place to work and had wonderful people.

>The reason kits were made in the first place was because hams liked
>building them, and minus the labour of assembly, they could be sold
>cheaper than ready built items. (And hams were always...errr frugal)

Again, not when you are dealing with low volumes. Heath did not export well. Many of the decision makers dealt with Illinois, Indiana, Michigan, and Wisconson as their primary sales area. I recall this in particular when they began talking about a major sales campaign to push the H-8 computer. The national blitz was four states.

>By the 1970's there was no longer any financial advantage in kits.

Heath finally began trying to sell the experience i.e. the pleasure of building your own equipment for six hours is cheaper than a Rock Concert (or whatever).

> tiny hole in the case.

Being that I've done this twice in several years of dealing with SCSI hard drives, I can make an educated guess at what happened. Plugging the drive interface cable in upside generally does no harm on floppies or IDE drives, but is the kiss of death for many SCSI drives. In both instances that I did this, it did destroy active components (heavy silicon odor). Unkeyed SCSI connectors have been pretty common in the past and contribute to this problem. One thing to look for is whether or not your host adapter supplies termination power and what pin that power would have been applied to...

The first time I did this it was a 48M Seagate that cost me $440 wholesale and because a friend wanted to try it on his Amiga from my Atari ST. (LONG time ago!)

-> Well, they basically priced themselves out of the market. Why would you
-> spend a lot of time building equipment that wasn't as good as stuff you
-> could buy off the shelf for less?

Gee, what would you expect in an five-band HF rig that cost $450?
There was nothing wrong with Heathkit's equipment. It was as good
as the BUILDER could build it. If the builder's skills were poor
then the resulting rig was poor. I bought and built many rigs
and pieces of test equipment from Heath with no problems that weren't
the result of my mistakes during construction. As I got better
at building their rigs got "better." Granted they didn't have all
the bells and whistles of the commercially built stuff but did you
really need all those bells and whistles? Over the air my HW-101
sounded just as good as my Yaesu FT-101 and still sounds as good
as my FT-890. (using the same mike) No, it won't do FM, AM or RTTY
but it does CW and SSB just fine.

->
-> > 73,
-> > -David-
-> > KC5WDR

-David,
- Financial advantage wasn't the operative word, education was. By building and
-aligning your own stuff you LEARNED about how it worked. Problem is that
-Americans have gotten lazy and are dumbing down, like it or not. If this wasn't
-happening rat-shack would not have taken over the market.
- Bill

You are right Bill, financial advantage wasn't the operative word. It
was Heath's decision during the beginnings of the computer boom to
put all their eggs in the computer basket. When they couldn't compete
they fell apart because they had basically dropped every other line
to support their computer line. When they found that they couldn't
keep up with the computer market they also found that all their kit

customers had gone elsewhere. Radio Shack almost made the same mistake. If it wasn't for their other lines they would have gone the way of Heath. If you've noticed Radio Shack doesn't sell their own line of computer equipment any more. As far as the lazy and dumbing down I don't think that had too much to do with it. Those who are dumbed down and lazy don't spend any time on HF anyway. ;)

1413. Old Radios with 201-A tube and variometer tickler (?) queskin...

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-23 00:00:00 UTC
From: nyoung@nova.wright.edu
Message-ID: <1996Sep23.114145@nova.wright.edu>
Source record: 102148

Cindy and I went to the local antique flea market yesterday and, while Cindy shopped for the perfect Martha-Stewart-lookalike-useless-piece-of-crap-nick-nack, I found a guy who had what looked like an old radio for sale. Talked him out of it cheap. Now all I need to do is figure out when it became what it is and who might have made it and where...

It's a one-tuber with a series cap to a large coil. The front panel has two open-contact switches that lead to taps on the coil. The top of the coil has a green-wire variometer with a front panel control knob. Two open rheostats, one to the tube (filament?) the other to the AF terminals (volume? regeneration?) and two pretty healthy capacitors on the front too. The pots have "CH" stamped on 'em. The caps are pretty normalish, some sort of "condensa.." something on one of 'em.

I suspect that the box has been through some sunlight or has been otherwise subjected to solar rays. The front panel appears to be ebonite and there is a grid of small holes on the panel, right in front of the tube. The panel is black behind the knobs, but otherwise is kinda brownish-yellow. ANd the labels have long since flitted off, so the only terminals marked are the ones for "telephones" and "aerial" and "ground." The knobs are Atwater-Kent look-alikes.

WHile I was carting this little box (wooden cabinet, piano hinge and latching bar lock to hold it open) around with Cindy, a couple guys about my age came up and said "It's a kit." "Figured that much," sez I, "'cause it's got no info inside as to how it came to be. No labels, no tested-logged-sold stickers on the inside cover." "Oh, they made a lot of 'em back in the 20s" said one guy. Then I saw the Zenith Transoceanic.

Oh, yeah: the tube has a filament. Sometimes you get lucky.,

Any hints on what I might have? After such a stunning description, most of youse is probably already gone on to the next interesting posting. But what the heck. I got the MRL #2 crystal set in a box. I may as well find out what this flea-market find is/was.

How many crystals does this radio have?
If it is one or two, it is impossible to convert to 10M (tHe PLL is
designed for CB especially)
If it has 3 crystals, It is much easier to convert.

1416. Help with UHF Design

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-23 00:00:00 UTC
From: Jack <jack@mrwint.demon.co.uk>
Message-ID: <3246D2B2.FD2@mrwint.demon.co.uk>
Source record: 102151

I'm studying the schematics for a 750mW 440 MHz UHF transmitter to try and improve my understanding of RF design. I've come across a problem and I'm not sure if it's the schematic or me.

The transmitter uses a Motorola MRF559 as it's PA operating in Class C. I've obtained the Data sheets from Motorola's Web Site and the spec states that ZOL for 0.75W at 12.5V on 440MHz is 49-j50 (The spec states that this is the 'Conjugate of the optimum load impedance into which the device output operates at a given output power, voltage and frequency'). This means that the load should look like 49+j50, Right?

The schematic looks like this (I hope it's understandable, first attempt):

```
----------------- 12.5V
| |
C L
C 100pF L 39nH
C L
| | 25nH 10pF
------------------LLL-------------CCC--------- 50 ohm OUT
| |
| C
--O MRF559 C 1pF
| C
| |
GND GND
```

I've analysed the output network by maths and checked the answer on a Smith Chart, and it appears that the impedance of the network is 22+j31 which I feel is a long way out from the suggested value. Could stray L and C make this much difference or am I overlooking something? Should I build the circuit with the suggested values or calculate my own?

Any help would be much appreciated, I've been thinking over this for days now and you're the only people I know to ask.

Many Thanks,

Mark.

I'm surprised no-one has mentioned the balanced transformer-feedback designs written up by Dallas Lankford and published in the IRCA "DX Monitor" and NRC "DX News". A 50-ohm input impedance RF-preamp variant was described by Rohde in one of his QST articles on modern receiver design. The Kiwa preamp is the same basic design.

These preamps can have very low intermodulation distortion, which translates to a high dynamic range, which is what you need for an active antenna. They do present a lower input impedance than one would like for a voltage probe active antenna, unfortunately.

Write to the NRC (http://wcoil.com/~gnbc/) and ask for their reprint catalog; that should list the article. I think it was entitled something like "High dynamic range loop preamp" or something like that. You should be able to buy the reprint for at most a few bucks.

Yes, there is a homebrew aspect to this response further down....

And what if, try as you might, you couldn't get the technical aspects of the tests right (many people can't)? Would you cry "discrimination" because, after all, why do you need to know what thosed damned transistor squiggles and Ohm's law thingies are? Only homebrewers need to know these things, not appliance operators. Who needs to know how an engine works to drive a car, after all? Why do you have to understand the components of a phase modulated TX when all you ever intend to do is key the mike on your Yeasu wonderradio?

I could make as big a case for removing most of the technical requirements as you are making for the removal of the code requirement. If successful, would we be better Hams? I don't think so.

Mark my words, if the CW requirement is removed, the technical requirement will follow. That would be a sad day.

And before anyone cries, "but it's alright for you, you have passed the tests", I'll point out that I have been a supporter of the code requirement both before and after writing my tests recently (a quick search using Deja News will verify this).

Again, I like the homebrew aspects, and there is no simpler homebrew starting point than a CW TX. The CW requirement encouraged me to enter, as I know there are many people out there with whom I can communicate using my freshly made homebrew TX. A selfish position, perhaps, but no more selfish than those who clammer to have the requirement removed because they cannot pass.

That's a good point Paul, but if the person stays within the AC current design limits of that winding (with the peak choke current) the core will be will be ok.

Another point worth mentioning is that if the transformer fails from shorted turns, the impedance of other windings is reduced.

Hello All,

This is a second post, since no one answered our previous one:

We're looking for a simple tunable 300-400MHz power oscilator design.
Minimal power output should be at least 50mW.
We were thinking about a simple GUNN DIODE oscilator, but these
devices are pretty hard to get and we're not sure they're suitable for
this frequency range.

Designs, anyone?...:-)

When responding, please email directly in addition to posting
here, so that no responses are missed.

How about a Mini-Circuits VCO followed by a MMIC amplifier? If you would rather build your own, try a grounded gate oscillator using a U310 JFET. Place a tuned-circuit in the drain with a small capacitor from the drain to source (2.2 pF?) and a 100 ohm resistor from the source to ground. The DC supply is connected to the other end of the inductor - bypass well! Tune the tank with back-to-back varactors coupled with the smallest capacitor values that give you sufficient tuning range. Take the output off the drain through a very small capacitor or tap the inductor at a low impedance point.

Hi,
I've used many JAN crystals over the years of all varieties, the latest in a Motorola Mitrek conversion to a 430 MHz packet link. They have always worked fine and always checked out to the specified accuracy for frequency. And yes they've bounced around in Florida from place to place which hasn't had any ill effect that I've noted on their quality control.

David,
Financial advantage wasn't the operative word, education was. By building and aligning your own stuff you LEARNED about how it worked. Problem is that Americans have gotten lazy and are dumbing down, like it or not. If this wasn't happening rat-shack would not have taken over the market.

Rodney,
I'm not sure of your intensions for this attenuator but I strongly suggest
building the active attenuator. Of course, if you are needed a calbrated att,
then the stepped version would be what you need but if it is for T-hunting,
I've had excellent results with the active att. Other articles I've read on
the circuit claim to give nearly 100dB of attenuation however I have found that
by changing the frequency of the receiver, you have practically infinative
attenuation.

I was able to purchase all of the parts in town and and quite possibly all of
them from Radio Shack (can't remember, it's been a while).

I just got an order of cores from Palomar Engineers. They will send out spec sheets for free and I don't think they have a minimum order (I ordered about $30 worth of cores). I also found a few cores from DC Electronics. They were quite a bit cheaper than palomar but they only carried a small selection. Amidon Associates may be able to help you. I have some info from them but have never ordered from them.

If its a good size power transformer and the primary is the first winding on the core. Cut out the secondary windings and replace them with a 3 or 4 turn secondary using some welding cable as the wire. Attach some very large alligator clips and use it to thaw frozen pipes. Dont leave it on to long or you will melt the solder joints.

Heath had an initial advantage when the first started in that the wiring in electonics was point to point and very time consuming. When PCBs were used and the boards were stuffed and wave soldered by machine that advantage went away. Within Heath, the development for a kit had to be paid off in two years of production. This was the standard and that set the kit price (we had an old PDP-8 that was pre-programmed with the accepted formula to generate the kit price). The problem was the volume. The volumes were in many cases for Ham equipment a few thousand a year. Also throw into the barrel that their was not a lot of money for test equipment. But.... it was a great place to work and had wonderful people.

>The reason kits were made in the first place was because hams liked
>building them, and minus the labour of assembly, they could be sold
>cheaper than ready built items. (And hams were always...errr frugal)

Again, not when you are dealing with low volumes. Heath did not export well. Many of the decision makers dealt with Illinois, Indiana, Michigan, and Wisconson as their primary sales area. I recall this in particular when they began talking about a major sales campaign to push the H-8 computer. The national blitz was four states.

>By the 1970's there was no longer any financial advantage in kits.

Heath finally began trying to sell the experience i.e. the pleasure of building your own equipment for six hours is cheaper than a Rock Concert (or whatever).

From outside the US I cannot comment on individual Xtals however:
Crystals that stop when cold? this is a symtom of crystals sealed in a
moist atmosphere. When the crystal gets cold the atmosphere in the
crystal reaches dew point and dew forms on the crystal adsorbing
vibrating energy and increasing resistance, the frequency also drops
50ppm or so. If your oscillator circuit is very active the crystal wont
stop but the freq still drops.
Crystals are best sealed in nitrogen with a -40 dew point.
Modern crystals are normally resistance welded like metal transistors ,
older processes use solder seal, not always bad. I have seen Xtals
sealed with heat shrink ! not so good.

In article <steve-2309961459310001@brainiac.hi.com>, steve@hi.com (Steve Byan) writes:

>I'm surprised no-one has mentioned the balanced transformer-feedback >designs written up by Dallas Lankford and published in the IRCA "DX >Monitor" and NRC "DX News". A 50-ohm input impedance RF-preamp variant was >described by Rohde in one of his QST articles on modern receiver design. >The Kiwa preamp is the same basic design.

Actually Rohde described it FIRST in RF Design magazine. I used transformer feedback pre-amps in the early 70's using CATV transistors.

>These preamps can have very low intermodulation distortion, which >translates to a high dynamic range, which is what you need for an active >antenna. They do present a lower input impedance than one would like for a >voltage probe active antenna, unfortunately.

The main advantage is low noise, the negative feedback does not deteriorate the noise figure. This is not a concern at HF except for the first stage, or following a passive mixer.

I use a simple high power low noise FET source follower at my voltage probe antennas, and catv bi-polar amplifiers on my loop arrays. I do NOT use transformer feedback with small loops. With the transistor running at very high gain, very little feedback is used so the feedback resistance does NOT deteriorate noise figure enough to be measurable in the overall noise performance. It's only when gain is greatly reduced by large amounts of negative feedback that transformer feedback has a noise advantage. All feedback has an IMD advantage, but with a small antenna we can't use much feedback or we won't have enough gain.

At HF, it's easy to have ambient EXTERNAL noise at the receiving site dominate the system noise, even with an non-resonant antenna only one or two feet long or diameter. No special "tricks" are needed.

>
>Big loss to homebrew and old gear folks I think.
>

JAN Crystals still makes FT-243 rocks (I'm sure they're more expensive
than $4 - $6 each, however).

I still find them from time to time at hamfests. I have never paid more
than $2.00 each for them, and usually it's $1.00 each.

Also, put out the word with as many people as you can that you're looking
for them. You'd be surprised how many people still have a few lying in
a drawer somewhere, unused and forgotten!

I have over 100 FT-243 crystals for 80m and 40m CW frequencies (many of
which will multiply into the 20m, 15m, and 10m bands as well). It's
taken years to build up this "library" of rocks, but I haven't spent much
money doing it.

Sorry, I don't have any extra crystals to offer you.

1437. What happen to Heathkit?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-24 00:00:00 UTC
From: wlfuqu00@service1.UKy.EDU
Message-ID: <199609241541.LAA27632@service1.cc.uky.edu>
Source record: 102169

It is simple. It is cheaper to manufacture something
than make a kit. Even in the old Heathkit catalogs there
were examples of this. There was an All-American 5 tube radio
that was cheaper to buy assembled than in kit form.
Today we often buy new electronic devices rather than have
them repaired. Often it cost more to repair them than to replace
them.

Howdee.

I've been looking for a compendium of mods for the Heath HW8 QRP rig.

It's been suggested that I get the book "HW8-Handbook" by the 73
magazine QRP editor. 73 Mag. doesn't have the book.

Can anyone point me to a source OR does anyone have a copy they would
sell?

1439. Help designing modulator for direct-to-skull work

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-24 00:00:00 UTC
From: raven1 <raven1@netaccess.on.ca>

Body handling: HTML body converted to readable text

I'm one of several thousand victims of electromagnetic harassment. One of the main 'tools' used by the harassers is audio-via-direct-RF-to-skull transmission mode.

In a nutshell, this mode uses very 'thin' (low duty cycle) pulses like the teeth of a comb with the peaks modulated by the audio waveform. High quality voice and other audio are transmitted this way.

I would like to use a moderate power (20 - 50 watts?) ham transmitter coupled to a special modulator to try to duplicate this technology as a first step in showing the public that this technology exists NOW, and not only works, but works amazingly well. (The 420-450 MHz band would be a likely candidate for carrier.)

Below is an amazing article from 1962, believe it or not, detailing successful tests of this mode. If you can't receive it all, please request a separate e-mail transmission from me at:

raven1@netaccess.on.ca

Most sincere thanks to all who read this - it is NOT a hoax. Anyone wishing detailed information on electromagnetic harassment in general can dial up this web site:

Note: This paper explains how voices can be beamed directly into an individual's head.

(*) Asterisks indicate unreadable characters in the original copy

--The intent of this paper is to bring a new phenomena to the attention of physiologists. Using extremely low average power densities of electromagnetic energy, the perception of sounds was induced in normal and deaf humans.

The effect was induced several hundred feet from the antenna the instant the transmitter was turned on, and is a function of carrier frequency and modulation. Attempts were made to match the sounds induced by electromagnetic energy and acoustic energy. The closest match occurred when the acoustic amplifier was driven by the rf transmitter's modulator. Peak power density is a critical factor and, with acoustic noise of approximately 80 db, a peak power density of approximately 275 mw / rf is needed to induce the perception at carrier frequencies 125 mc and 1,310 mc. The average power density can be at rf as low as 400 _u_w/cm2. The evidence for the various positive sites of the electromagnetic energy sensor are discussed and locations peripheral to the cochlea are ruled out.

Received for publication 29 September 1961.

A significant amount of research has been conducted with the effects of radio-frequency (rf) energy on organisms (electro- magnetic energy between 1 kc and ** Gc). Typically, this work has been concerned with determining damage resulting from body temperature increase. The average power densities used have been on the order of 0.1-t w/cm2 used over many minutes to several hours.

In contrast, using average power densities measured in microwatts per square centimeter, we have found that ****r effects which are transient, can be induced with rf energy. Further, these effects occur the instant the transmitter is turned on. With appropriate modulation, the perception of different sounds can be induced in physically deaf, as well as normal, in human subjects at a distance of inches up to thousands of feet from the transmitter. With somewhat different transmission parameters, you can induce the perception of severe buffeting of the head, without such apparent vestibular symptoms as dizziness or nausea. Changing transmitter parameters down, one can induce a "pins-and-needles" sensation.

Experimental work with these phenomena may yield information on auditory system functioning and, more generally, in the nervous system function. For example,

this energy could possibly be used as a tool to explore nervous system coding, possibly using Neider and Neff's procedures (1), and for stimulating the nervous system without the damage caused by electrodes.

Since most of our data have been obtained of the "rf sound" and only the visual system has previously been shown to respond to electromagnetic energy, this paper will be concerned only with the auditory effects data. As a further restriction, only data from human subjects will be reported, since only this data can be discussed meaningfully at the present time. The long series of studies we performed to ascertain that we were dealing with a biological significant phenomena (rather than broadcasts from sources such as loose fillings in the teeth) are summarized in another paper (2), which also reports on the measuring instruments used in this work.

The intent of this paper is to bring this new phenomenon to the attention of physiologists. The data reported are intended to suggest numerous lines of experimentation and indicate necessary experimental controls.

Since we are dealing with a significant phenomenon, we decided to explore the effects of a wide range of transmitter parameters to build up the body of knowledge which would allow us to generate hypotheses and determine what experimental controls would be necessary. Thus, the numbers given are conservative; they should not be considered precise, since the transmitters were never located in ideal laboratory environments. Within the limits of our measurements, the orientation of the subject in the rf field was of little consequence.

Most of the transmitters used to date in the experimentation have been pulse modulated with no information placed on the signal. The rf sound has been described as being a buzz, clicking, hiss, or knocking, depending on several transmitter parameters, i.e., pulse width and pulse-repetition rate (PRF). The apparent source of these sounds is localized by the subjects as being within, or immediately behind the head. The sound always seems to come from within or immediately behind the head no matter how the subjects twists or rotates in the rf field.

Our early experimentation, preformed using transmitters with very short square pulses and high pulse-repetition rates, seemed to indicate that we were dealing with harmonics of the PRF. However, our later work has indicated that this is not the case; rather, the rf sound appears to be incidental modulation envelope on each pulse,

as shown in Fig 1.

Some difficulty was experienced when the subjects tried to match the rf sound to ordinary audio. They reported that it was not possible to satisfactorily match the rf sound to a sine wave or to white noise. An audio amplifier was connected to a variable bypass filter and pulsed by the transmitter pulsing mechanism. The subjects, when allowed to control the filter, reported a fairly satisfactory match. The subjects were fairly well satisfied with all frequencies below 5-kc audio were eliminated and the high-frequency audio was extended as much as possible. There was, however, always a demand for more high-frequency components. Since our tweeter has a rather good high-frequency response, it is possible that we have shown an analogue of visual phenomenon in which people see farther into the ultraviolet range when the lenses is eliminated from the eye. In other words, this may be a demonstration that the mechanical transmission system of the ossicles cannot respond to as high a frequency as the rest of the auditory system. Since the rf bypasses the ossicle system and the audio given the subject for matching does not, this may explain the dissatisfaction of our subjects in the matching.

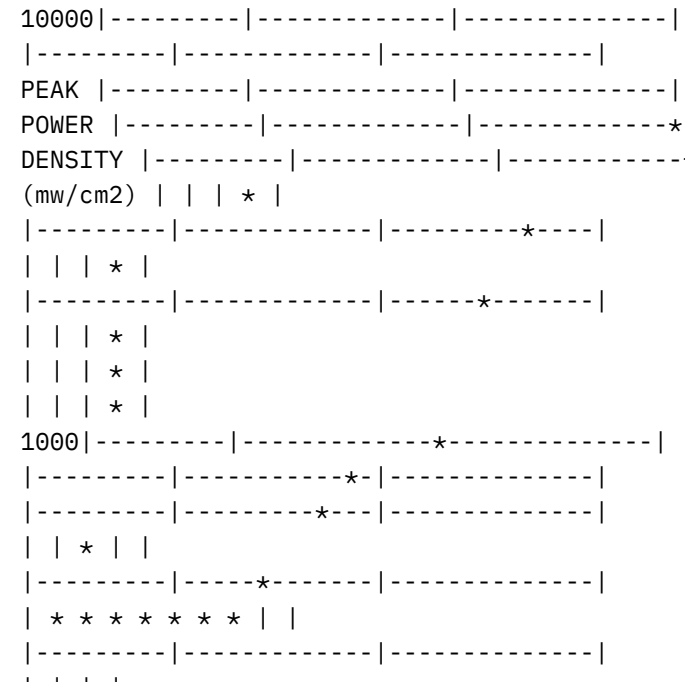

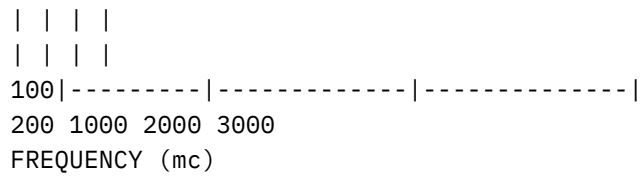

FIG. 5. Microwave power distribution in a forehead model neglecting resonance effects and considering only first reflections (from Nieset et al. (5), modified).

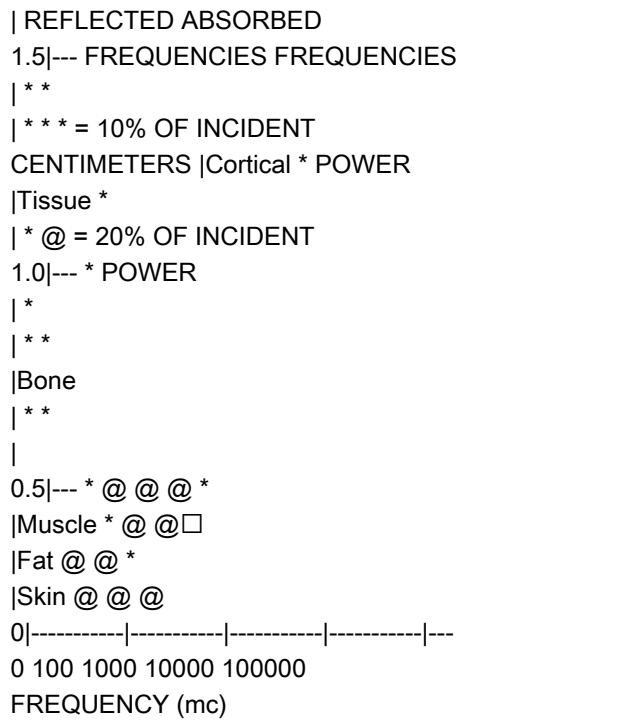

FIG. 6. Area most sensitive to electromagnetic energy (shaded portion).

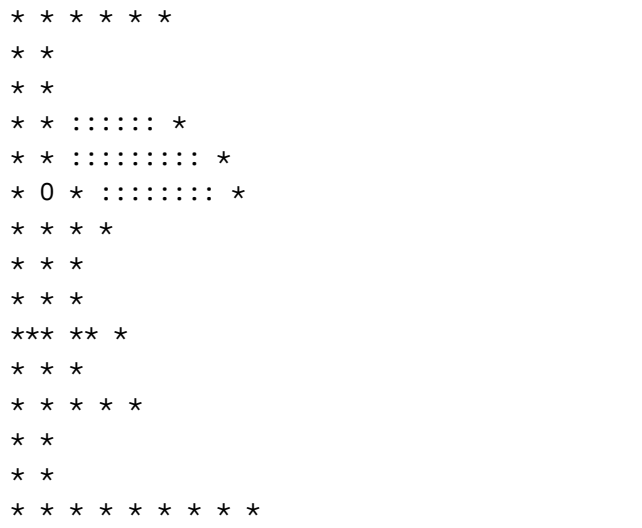

At one time in our experimentation with deaf subjects there seemed to be a clear relationship between the ability

to hear audio above 5 kc and the ability to hear rf sounds. If a subject could hear above 5 kc, either by bone or air conduction, then he could hear the rf sounds. For example, the threshold of the subject whose audio gram appears in Fig. 2 was the same average power density as our normal subjects. Recently, however, we have found people with a notch around 5 kc who do not perceive the rf sounds generated by at least one of our transmitters.

THRESHOLDS

As shown in Table 1, we have used a fairly wide range of transmitter parameters. We are currently experimenting with transmitters that radiate energy at frequencies below 425 mc, and are using different types of modulation, e.g., pulse-repetition rates as low as 3 and 4/sec.

In the experimentation reported in this section, the ordinary noise level was 70-90 db (measured with a General Radio Co. model 1551-B sound level meter.) In order to minimize the rf energy used in the experimentation, subjects wore Flent antinoise ear stoppers whenever measurements were made. The ordinary noise attenuation of the Flents is indicated in Fig. 3. Although the rf sounds can be heard without the use of Flents, eventhough they have an ambient noise evel of 90 db, it appears that the ambient noise to some extent "masked" the rf sound.

Table 2 gives the thresholds for the perception of the sounds. It shows fairly clearly that the critical factor in the perception of the rf sound is the peak power density, rather than the average power density. The relatively high value for transmitter B was expected and will be discussed below. Transmitter G has been omitted from the table since the 20-mw/cm2 reading for it can be considered only approximate. The field-strength-measuring instruments used in that experiment did not read high enough to give an accurate reading. The energy from transmitter H was not perceived, even when the peak power density was as high as 25 w/cm2.

When the threshold energy is plotted as a function of the rf energy (Fig. 4), a curve is obtained which is suggestive of the curve of penetration of rf energy into the head. Figure 5 shows the calculated penetration, by frequency of rf energy, into the head. Our data indicate that the calculated penetration curve may well be accurate at the higher frequencies but the penetration at the lower frequencies may be greater than that calculated on this model.

As previously noted, the thresholds were obtained in a high ambient noise environment. This is an unusual situation as compared to obtaining thresholds of regular□ audio sound. One recent experimentation leads us to believe that, if the ambient noise level were not so high, these threshold fields strengths would be much lower. Since one purpose of this paper is to suggest experiments, it might be appropriate to theories as to what the rf sound threshold might be if we assumed that the subject is in an anechoic chamber. It is also assumed that there is no transducer noise.

Given: As a threshold for the rf sound, a peak power density of 275 mw/cm2 determined in an ambient noise environment of 80 db. Earplugs attenuate the ambient noise 30 db.

If: 1 mw/cm2 is set equal to o db, then 275 mw/cm2 is equal to 24 db.

Then: We can reduce the rf energy 50 db to -26 db as we reduce the noise level energy from 50 db to o db. We found that -26 db rf energy is approximately 3 _u_w/cm2.

Thus: If an anechoic room, rf sound could theoretically be induced by a peak power density of 3 _u_w/cm2 measured in free space. Since only 10% of this energy is likely to penetrate the skull, the human auditory system and a table radio may be one order of magnitude apart in sensitivity to rf energy.

RF DETECTOR IN AUDITORY SYSTEM

One possibility that seems to have been ruled out in our experimentation is that of a capacitor-type effect with the tympanic membrane and oval window acting as plates of a capacitor. It would seem possible that these membranes, acting as plates of a capacitor, could be set in motion by rf energy. There are, however, three points of evidence against this possibility. First, when one rotates a capacitor in an rf field, a rather marked change occurs in the capacitor as a function of its orientation in the field. When our subjects rotate or change the positions of their heads in the field, the loudness of the rf sound does not change appreciably. Second, the distance between these membranes is rather small, compared with the wavelengths used. As a third point, we found that one of our subjects who has otosclerosis heard the rf sound.

Another possible location for the detecting mechanism is in the cochlea. We have explored this possibility with nerve-deaf people, but the results are inconclusive due to factors such as tinnitus. We are currently exploring this

possibility with animal preparations.

The third likely place for the detection mechanism is the brain. Burr and Mauro (6) presented evidence that indicates that there is an electrostatic field about neurons. Morrow and Sepiel (7) presented evidence that indicates the existence of a magnetic field about neurons. Becker (personal communication) has done some work indicating that there is longitudinal flow of charged carriers in neurons. Thus, it is reasonable to suspect that possibly the electromagnetic field could interact with neuron fields. As yet, evidence of this possibility is inconclusive. The strongest point against it is that we have not found visual effects although we have searched for them. On the other hand, we have obtained other nonauditory effects and have found that the sensitive area for detecting rf sounds is a region over the temporal lobe of the brain. One can shield, with a 2-in.2 piece of fly screen, a portion of the stippled area shown in Fig. 6 and completely cut off the rf sound.

Another possibility should also be considered. There is no good reason to assume that there is only one detector site. On the contrary, the work of Jones et al. (8), in which they placed electrodes in the ear and electrically stimulated the subject, is sufficiently relevant to suggest the possibility of more than one detector site. Also, several sensations have been elicited with properly modulated electromagnetic energy. It is doubtful that all of these can be attributed to one detector.
As mentioned earlier, the purpose of this paper is to focus the attention of physiologists on an unusual area and□ stimulate additional work on which interpretations can be based. Interpretations have been deliberately omitted from this paper since additional data are needed before a clear picture can emerge. It is hoped that the additional exploration will also result in an increase in our knowledge of nervous system functions.

I am starting to see some good answers to this question posted
so I will not repeat them, but I do want to comment that I dont
think there are any Gunn diodes that will work in this frequency
range. Lowest frequency for Gunns I've seen is about 4GHz but
I could be wrong. There was an interesting device called a tunnel
diode which might work, but I've not seen one used in years.
Anybody know what happened to the tunnel diode?

> the screws into. Is it critical that these are brass & not some other
> metal?

I built the RF attenuator using brass nuts to hold the cover in place.
Using a RF signal generator and spectrum analyzer, I observed that the
cover
did not help isolate the sections and there was some signal getting thru
from the input to the output port.

I removed the cover and brass nuts. I used a thin brass sheet which was
cut to fit the bottom of each section. I carefully soldered each brass
sheet section in place. Make sure to solder all around the brass sheet.
This helped seal each section so that it was RF tight. I tested the unit
again and the RF attenuator performed extremley well. With 20 dB
sections,
I was able to obtain about 120 dB of RF attenuation from 1MHz to 1GHz.

And just to add fuel to the already inflamminatorized discussion: I've been playing CW since around 1968, when I got my licence. This was after the USN had told me that I was gonna be a radio operator but sent me to teletype school (no cw) instead. So I had to learn the CW the same way many do: listen and listen and listen and pink rabbits with bad fists. But I wanted to play HF and I wanted to play DX and I wanted the damn ticket. So I learned to copy at 5 wpm. Then I bought a keyer and discovered that I could send at 15 wpm and copy at 8. So I learned to copy at 17 and passed the general. Then the advanced. And since it's been a while since I chased some guy up the warp scale of CW, that's where I is today: an advanced ticket holder who would, if he could find the time, study all the transistor squiggles and learn to copy cw at 20+ (which I could do back in '72 when I left the USN).

Actually, it all comes down to something I read once in a _Playboy_ magazine. (We all read _Playboy_ in the Navy. It was the only source of good literature and cogent discussion of current event topics. Yeah, right.) Once some years ago I came across a story by Kurt Vonnegut. I think I read it in _Playboy_. The story was called "The Handicapper General." At least that's what I remember, even if it might just have been the name of one of the characters. The Handicapper General.

The Handicapper General was a government official who went around putting weights on the best ballerinas so that none would be better than an a priori average. Same with speakers: special dental and tongue implants so that their words would not sound any better than any other speakers. Clamps and bondage on the hands of writers. Limited vocabulary and spell-checkers too. Everyone was averaged out by the Handicapper General.

So you have a choice: you either get past the basic crap, the CW or the theory, and you get on with enjoying whatever part of the hobby you like, be that satellites or QRPp on 1.75 km. You're different. You cared enough to go through the basic training to get the licence.

Or you can water it down, one way or the other, with no CW requirements or no technical knowledge requirements and you end up with CB (or some pandemic equivalent) that has been averaged out by the Handicapper General.

Me, I'd rather know that my frontal lobe and my ability to decipher signs and sounds somehow went beyond my natural ability to control what is to all other animals just food barks. Simple choice. Signs and significance or gibbering cacophony.

My first guess would be that it's a poorly formed label for a NEC chip.

Only way to find out is to get the manual. Something that Radio Shack
is really pretty good at. One way is to get the local salesdroid to
order it, another is to get it from "Tandy National Parts". They
have an 800 number, take plastic, and can get most any part for
Tandy stuff. I got the number by calling their 800-The Shack number
and futzing around in the voice mail maze until I got to an operator
who gave it to me. Can't find it now, though...

The surplus outfit that usually has them in their ads is Timeline. They advertise in Circuit Cellar Ink, sometimes in Nuts & Volts, and in the issues of Electronics Now that have the "Electronic Shopper" quarterly? supplement. They're on the web somewhere, I just read that their URL changed. $5 to $25 depending on size.

There's copies of a FAQ on http://www.paranoia.com/~filipg or on ftp://ftp.ee.ualberta.ca (in the pub/cookbook, ???)

There was also a two part article in Radio-Electronics a few years back (summer of 1989?).

Bill and the group,

I want to interject a few quick comments from the viewpoint of a former Heathkit employee. (I was the Assistant Manager of the Mission, Kansas Heathkit retail store for a few years...)

#1 We felt that Heathkit was always treated as a "poor stepchild" by the firms that owned it. It got passed
around from owner to owner and could not maintain a consistent marketing focus or product line. During
Heath's final years, it was always "SomeConglomerate DBA Heathkit". For example, we honestly felt that
Zenith bought us for our "cutting edge" PC technology (everybody remember the H-8 and H-88? H-DOS?
CP/M?), but didn't really care about the other established facits of our company.

#2 We felt that Heath's upper management failed to forecast or see significant changes in the market we
served. Mr. Fuqua is right, it is more expensive to produce a kit version of a consumer product. I'd extend
that line of thinking by stating that it's MUCH more expensive both on the "front-end" (components, cabinet,

instructions, packaging, etc....) and the "back-end" (technical support of client during and after
construction, parts stock at numerous retail locations, counter time supporting client rather than moving
product, etc, etc...) *BUT!!!!* The concept can work if you provide a unique product with obvious features
that set it apart from similar pre-assembled consumer goods.

I don't want anyone to think I didn't enjoy my tenure at Heathkit and give my all to try to make it work! I did!
Many of the store "demo units" were my handiwork as I enjoyed building kits just as much as any other
techno-type person. All of us were saddened by the decline. I still drive by the old store, now a pawnshop,
and remember the glory days of crowds on the day we released new kits, amatuer radio club meetings,
unloading the truck from Benton Harbor... Oh well.....

Well folks the results are in! After observing the stats of the
downloaded FCC database with which Microsoft Access, Foxpro,
etc...were used we now know that 78%.....I say again 78% of the U.S.
Amateur Radio operator population is of the coded variety. Only 22%
of the hams are no code technicians. That is 1/5th. I think the
numbers of no-coders will have to grow for there to a significant
impact here.

Now, realistically not everyone of that 78% is active...but I bet
neither is the entire 22% of the uncoded population.

What say ye naysayers about that?

well, it's more than just price or lazy people as well (i kinda find that sort of comment a bit self serving and degrading for what it's worth). it's things like increasing specification requirements as well. ham gear not ok to use in commercial bands unless you get commercial gear that can be used in the ham bands for example.

you have people hustling for every penny they can get..why do they have to spend weeks building a TV when you can buy one for less...

radio shack is a dominant force because the existing amateur radio companies aren't geared up to work in a sales environment like radio shack has to deal with. if radio shack as 3000 stores and needs 2 radios per store, that's 6000 radios just to stock the stores....i suspect that the makers and dealers have been "Comfortable" and were blind sided by radio shack.

Louwers (louwers@stevin) wrote:
: We think that recovery would be much easier if we had a kind of FOX
: hunting transmitter in it. So we are looking for a _small_ transmitter
: (144 MHz) design for our rockets. Range should be about 5-10 Km's.

: Does anyone of you have a good design for such a small transmitter? Preferably
: with PCB layout. Any help is greatly appreciated.

Maybe I can elaborate Jeroens intentions here a little bit. When our rockets come down, they either descend on a parachute or they strike when the recovery fails. This brings us to one more criteria: can withstand high 'G' forces, which makes very sensitive parts useless.

When a rocket is landed, there are thus two obvious places for us to look; either at the ballistic end of the trail where the rocket impacted, or at the meteorilogical end where the wind brought it.

These things are not small, so fairly easy to find. The only problem is that the people who own the land (department of defense) don't allow us to strawl through the land to look for them. A homeing transmitter enables us to hunt for the rocket in a specific direction.

Concerning the range Jeroen indicates I think it's a bit of an overkill to be able to scan a 10km range for a rocket; 1 to 3 km should be more then enough. Even if we 'loose' the rocket from the launchers standpoint, we'll pick up a signal near the two expected locations.

One of our major concerns is that we cannot 100% assure that the rockets land on the designated area (3km wide, 8km long). If either the militaries or an innocent bystander finds the rocket first, we are in big trouble.

The sole purpose of this setup is to find the rocket back as soon as possible.

Here are some of the criteria listed:
- Small; must fit in a 40mm tube easily.
- Impact resistant; shock sensitive parts are undesireable.
- High G loads resistant; launch acceleration runs close to 50G
- Light; will be airborne, so no heavy batteries and components can be used.
- Direction sensitive; we'll have to be able to locate it by means of a simple receiver.
- Attitude insensitive; It should be locateable either lying on the ground or hanging from a tree (or sticking in the dirt).
- Simply reproduceable; we have a lot of rockets.
- Antenna problems expected with metalic body-tubes. Any idea for this problem is highly appreciated.
- Use of 144Mhz is required.

What we had in mind where these little transmitter posts used by radio amateurs to setup a game where people had to try to find the transmitter only by using a simple direction sensitive receiver.

Another application that comes to mind is the radio beacon used by wildlife preservists to tag certain animals and then track their whereabouts. These things are very small from the transmitters point of view, and very trackeable from the receivers point of view.

Any suggestions, and I mean ANY are welcome.

I'm considering adding a digital frequency readout to my old analog SWR. I like the old beast (Hallicrafters SX-28A) and don't plan to give it up, since it does go up to 42MHz and I'm hard pressed to find a SWR that covers the freqs above 30MHz. I'm wondering: a)would a standard digital frequency counter work; b)if so, where would I need to connect the input, and c)whether or not I'd need to build an IF stage for the counter so I'd get the proper readout. This is a rackmountable unit, and I'm considering putting this project in a 1U rack box. If I can do it with a standard freq. counter, does anyone have schematics for a homebrew unit?

TIA

You can measure the variable local oscillator frequency with any counter
that covers the range and has sufficient sensitivity. The number you
get will differ from the received frequency by the value of the
first intermediate frequency following the local oscillator. The
counter frequency will usually be higher than the received frequency,
but in some receivers or bands it may be lower.

Around twenty years ago there were some counters made which had a
programmable offset so that the value of the intermediate frequency
was automatically added or subtracted from the local oscillator
frequency before it was displayed. I don't know if any currently
available counters have this ability.

Try the January 1980 issue of QST. As I recall, there were about five errors in the schematic which became obvious when comparing components to their data sheets.

Also, Robert Foxworth wrote a number of articles for the National Radio Club about building digital displays and hooking them up to vacuum tube based receivers. They have a website at:

http://alpha.wcoil.com:80/~gnbc/

Good luck!

Don't be so ridiculous, What do you call nailing a tube
to a breadboard, strapping a few caps and coils around it
until it transmits or receives? By your standart it could not
possible have been homebrewing.

Not sure where you live, but if you're in one of the cooler climates,
you may be able to get aerosol cans of it in hardware/building supply
stores. Here in Canada, its used as exterior insulation around
houses (typically to fill gaps where the foundation and the siding
join).

This stuff turns almost rock hard once it has cured, I would think that
foam-rubber would be more useful for your purpose since it's flexible.
Not real sure where you can get this stuff, my last source dried up
2 years ago. I know it's available, just can't remember where to get
it (it's made by Dow Chemical I think).

regards,
Dean.

Mr. Burhans has retired. He wrote many articles for the "Lowdown" which
is the monthly paper put out by the Lowfering Group. He especialized in
preamp antennas designs. I can look up the address of Lowdown if there
is any interest. He also wrote many articles for the Ham Radio public,
but he has officially quit all business.

144 MHz is out of the question - unless you have licensed radio amateurs in
your rocket builders group. Even then, you'll need a special permit i think.
144 MHz is an exclusive amateur band - no other parties allowed.

However, there is a ISM band at 433.920 MHz +/- 0.2% where you can use 10 mW
transmitters. Also on 2450 MHz there is such a piece of spectrum. Look in
the Conrad catalog for more information about transmitters and receivers for
these frequency's.

In theory this could not happen because the oppsite side of the 50-pin cable connector is not-connected - specially for this purpose. I have often reverse-connected scsi devices with no smoke signs. Sometimes the 5V fuse in the terminator power line blows. This can happen if you connect an unpowered scsi device which has no series diodes on an active scsi bus.

1474. FS:DC Plugs:Kenw,Icom,Alinco,Yaesu

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-25 00:00:00 UTC
From: n2cjj@undefined
Message-ID: <1996Sep25.205000.1698720@undefined>
Source record: 102206
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.swap

I have found a source for those DC power cord plugs. The ones I've got
have 6 pins, male plastic with metal female (barbed) inserts.

The plug fits most 12VDC HF radios:
Icom 720, 735, 706..and alike, newer Yaesu and Alinco DX70.
Kenwood-TS120, 130, 140..430, 440, 450..850,..TS50,60, 660, 670...and alike.

Make your own power cord yourself, YOUR WAY!
Crimp or solder, long or short, heavy gauge wire, purple with polka-dots...

I'm offering the 6 position plug with 6 inserts for $4 each,
or the deal 3 for $10. All prices include postage in the US.

To order, kindly send a check to:

R. Langston
286 Hudson Street
Cornwall-on-Hudson, N.Y. 12520

You can also email me for info at: n2cjj@ibm.net

It's a great deal if you use one rig at home, in the car and at work and
are stuck dragging one power cord all over....

I still can't believe AES, HRO and others get $30 for a power cord. HiHi!

I don't think I've ever seen catalog listings for tunnel diodes, and they still might have been available somewhere back in 1971 when I became interested in electronics. The place to start would be to find who made tunnel diodes when they were in vogue, and try those companies today (or those that still exist). Start off with old data books, which you cn still find at hamfests (and maybe local ham clubs if they have kept a library).

A few years ago, somebody asked me if I had any tunnel diodes, because somebody he knew needed some to fix an old oscilliscope. You're really in a bind if you have a commerical piece of equipment that used them, since if you're building you can use something else (and there may not be a particularly good reason to use tunnel diodes for new stuff, esepcially if you can't find them).

The friend had recalled that I had once bought a huge bag of surplus diodes at a hamfest, and some of them "had similar packages". Not a great reason for thinking of them, none of them were labeled, but it is a thought. Find a curve tracer, find a sample curve for a tunnel diode, and start checking various diodes you can find to see if you can come up with something that somehow works the same way by accident.

People have done this sort of thing with other diodes.
Varactors/varicaps come to mind, since over the years I've seen plenty of articles about using common diodes as varactors. Zeners likewise. So there always is the slight possibility that you could stumble over a tunnel diode this way. Experimentation, after all, is the amateur way.

If you do find something this way, let the rest of the world know.

Source record: 102209

Emtech has a new QRP transceiver kit available for only $75, which my ham supply company just started to carry. You can order either the 80, 40,30, or 20 meter version. It is a superhet single signal receiver, with a variable crystal filter (available as an option for $20). The transmiter will put out 4-5 watts max, and adjustable down to the MW range. This rig will transmit and receive throughout the CW portion of the band. The keying and muting is very smooth and features solid state antenna switching. The rig also comes with full QSK keying. You supply the cabinet, power plug,and knobs. The rig is guranteed to work, as it is put together and tested in steps, you should not have any surprises. Full e-mail and phone tech support is available if needed.

If interested send me an e-mail and I'll provided more details.

Source record: 102210

Hello Carl!
I would recomend you to use something else for shock-absorbant.
The substances used to make urethane foam is not very healthy,
one of the substances is called MDI or methyldiisocyanate, and
it causes life-lasting asthma and other lungdamages.
It does'nt smell much, so you'll already be poisoned before you
know it...
In factory-maid foam that is fully cured, this substance is
fully locked into urethane, but it's very tricky to get the right mix.
If there's any unreacted MDI left it will slowly evaporate and
I wouldn't be in the same room as that foampiece...
Here in sweden it's no longer legal to sell it for private use.
I suggest that you use styrofoam instead, cutting it to the right
shape with a hot wire.

good luck //Lars (SM4RZW)

I did a simular, but probably not that sever a change by pulling the spindle drive motor out of a 5 1/4 floppy drive and the associated controller, and modified the pully to get the center adjustment at 1 7/8 ips so I could change the speed of the tapes for special effects.

If you only need the single slow speed, I would do it mechanically with different pully's and possibly a jackshaft to replace the current moter.

BTW an VCR with a dead video head makes a pretty good 5 hour audio recorder if you can spare the space.

Have you tried contacting the ARRL? I wrote asking for some reprints of some QEX articles. To my surprise, they sent me complete back issues. The fee was quite nominal.

BTW, the ARRL can supply photocopies of articles from QST. I recently purchased a photocopy of Beverage's original 1933 (or was it 32?) QST article from them. The service was quick and economical.

I have inherited a few from my Dad's old electonics collection. All were made by G.E. (and were made possible by the procedure in one of his patents!).

I don't have the part #s here, though I know all are Ge-Au devices. I have a few dozen total, three or four different types, and I'm willing to part with them for a reasonable price.
